THE Registrar General's return for the first quarter of 1964 shows that 220,000 live births were registered in that quarter as against 222,000 in the corresponding quarter of last year (*The Registrar General's Quarterly Return for England and Wales: Births, Deaths and Marriages; Infectious Diseases; Weather; Population Estimates, Quarter ended 31st March*, 1964. Pp. 28 (No. 46, 1st Quarter, 1964.) (London: H.M.S.O., 1964.) 2*s*. 6*d*. net). However, Easter fell in the last week of March, and this may have delayed some of the registrations. The preliminary seasonally adjusted figure shows 213,000 births, as against 212,000 for the corresponding quarter of 1963; this is slightly lower than the figure for the last quarter of 1963 (213,300) and below the peak figure for the third quarter of 1963 (215,400). The death rate in the quarter was low at 13·4, reflecting the relatively mild winter. Infant mortality at 22 per 1,000 live births is once again a record low figure for the first quarter. It will be interesting to see whether the figures for the second quarter of 1964 will show a continuation of the decline in the number of births and of the birth rate. The report contains, as is usual in March, a brief analysis of causes of death in 1963. There were only 7 deaths from acute poliomyelitis, the lowest number ever recorded, compared with 18 in 1962, and an annual average of 262 in 1951–53. Deaths from lung cancer increased by 3 per cent for men and 5 per cent for women, compared with 1962, whereas deaths from all malignant neoplasms increased by only 0·8 per cent. Motor vehicle accidents accounted for 6,400 deaths compared with 6,300 in 1962 and 6,600 in 1961.

Radio-isotopes in Hydrology

THE report of the panel on the use of isotopes in hydrology which met in Vienna during December 17–21, 1962, has now been issued (Technical Report Series, No. 23: *Isotope Techniques for Hydrology*. Pp. 36. Vienna: International Atomic Energy Agency; London: H.M.S.O., 1964. 21 schillings; 6*s*.; 1 dollar). More detailed discussions on some of the techniques mentioned by the panel were presented at an International Atomic Energy Agency symposium in Tokyo during March 5–9, 1963, and are published in *Radioisotopes in Hydrology* (I.A.E.A., Vienna, 1963). Ground-water dating techniques, including carbon-14, silicon-32 and tritium dating, are discussed in detail in the report, together with short-term ground-water tracing by techniques involving stable isotopes and activation analysis. It is recommended that the exchange of carbon between the liquid and solid phases in ground-water be investigated by tracing experiments in which tritium in tritiated water and carbon-14 as bicarbonate are used simultaneously. There are many unresolved questions regarding ground-water recharge rates, which depend on climate, season, geography, geochemistry, topography and vegetation, and until more is known the interpretation of ground-water age from tritium concentration data must be treated with caution. One section of the report deals with field experiments, covering investigations in the Snake River Plain, Idaho; an underground connexion in New Mexico; the determination of an aquifer by multiple-well tracing; and reservoir leakage, and another section with specific ground-water problems in Greece, on Kilimanjaro, and in the desert.

The panel concluded that isotope-technique applications to hydrological problems have been somewhat useful in the understanding of the nature of the hydrologic cycle and in the solution of specific engineering problems. However, additional research and development are required on the part of both hydrologists and isotope specialists, preferably working together as teams, to ensure the proper synthesis of scientific advances in their respective fields and the translation of these advances into practical technology. In particular, it considered that the present International Commission on Radiological Protection values, which are used as standards for exposure for large populations and which are based on long-term exposure, are too restrictive for short-term experiments such as are required in hydrological investigations.

Isotope Dilution Analysis

THE monograph *Radioactive Isotope Dilution Analysis* is one of the series of occasional publications of the Radiochemical Centre, Amersham (Pp. 12. Amersham: The Radiochemical Centre, 1964). Classical methods of chemical analysis generally rely either on the quantitative isolation of the component to be determined or on the measurement of some specific chemical or physical property of the component which is not obscured by other substances present. These methods often fail with more complex mixtures, and then isotope dilution analysis may be suitable. The basic principle is that if a radioactive tracer is mixed with the corresponding unlabelled compound the amount of activity per gram of the substance will be reduced, and that if the reduction per gram is measured the amount of diluting material can be calculated. The calculation and method of procedure are explained in the monograph and illustrated by an example. New developments in the field of dilution analysis, particularly derivative dilution where it is necessary to determine one component in the presence of several others, and saturation analysis which involves the use of a binding agent specific for the compound being determined, are explained in some detail. The examples discussed are mainly of organic substances but, as is shown in the final section of the monograph, direct isotope dilution can be applied equally well to inorganic substances. The monograph is not only an excellent introduction to the subject of radioactive isotope dilution analysis but also a valuable laboratory guide for those who wish to make use of the technique. There is a list of 25 references from which additional information can be obtained.

Solid-state Physics

THE *Bulletin de la Société Belge de Physique* is published by the Belgian Physical Society and records the proceedings of meetings on special topics organized by the Society. Regular members of the Society receive the *Bulletin*, but non-members can subscribe at 400 Belgian francs per series of six issues. The number of issues per annum ranges from four to six. The March 1964 issue (Series 4, No. 1) contains the proceedings of the annual meeting on "Solid-state Physics", held in Brussels on October 11, 1963. There were 21 contributions and these, some in abstract or summary form, are printed in English in the issue.

Albright Magazine

THE ingredients of a successful house journal of the type and quality nowadays sponsored by leading industrial concerns in Britain and overseas would appear to be attractive format and presentation, a nice balance between articles of technical and general interest and those concerned with the social activities of employees, high-quality illustration (sensitive blending of black and white and colour), and what may be best described as 'extra-mural' appeal. Circulation of magazines of this type, in many long-established and successful ventures, goes far beyond the patronage of the employees for whom they were primarily instigated, and deservedly so. The merits of these periodicals are that by means of informative articles, lavishly illustrated by photographs and diagrams, and written by administrative and technical experts, often outside the organization concerned, business, technology, general knowledge, and the social humanities are happily blended to the advantage of all concerned. As a tangible means of promoting *esprit de corps* and good staff relationships, such projects can scarcely be bettered. A comparative newcomer to the library of British house journals is the *Albright Magazine*, a bi-monthly periodical published by the well-known Albright and Wilson group of companies with a wide field of chemical and allied interests. The first number appeared in February 1964, to be followed by the April, June and, to date, August issues. A survey of these four issues proclaims at once that a high standard of production was initially aimed at, and certainly achieved, and that it persists. This journal has originality plus all the ingredients mentioned here. As it appears to be the policy of the editorial board not to publish regular editorials, the first issue, likewise the second, was not introduced from the 'chair'; it was as though the *Magazine* just happened, leaving the reader to judge its merits. However, in the June issue, the Editor relents and gives the reader a glimpse of the policy behind this project, particularly information on how the first two numbers had been received. Generally, the reception of this publication has been extremely good, including comments from an independent critic well accustomed to reviewing house journals. Two points in presentation, however, have been raised: the use of the + sign in place of an ampersand connecting Albright and Wilson, and the 'readability' of the sans serif type so far used in the text. The writer of this note frankly considers the former rather ugly and incongruous; the matter of type, on which the Editor asks for comments, is largely a matter of opinion; at first sight it appears rather formal, like some government specifications, and not so easy to the eyes as many house journals. Apart from these queries, it will be surprising if in the next National House Journal Competition (one has already been held for 1964) the *Albright Magazine* does not receive an award for merit, which it undoubtedly deserves.

Mechanizing Library Services

THE June–July issue of *Science Information Notes* (6, No. 3; 1964), issued by the National Science Foundation, records the commencement of an investigation, under an arrangement by the Council on Library Resources, to demonstrate that bibliographic information, suitably punched into a perforated paper-tape record by a tape-producing typewriter, can be reproduced in any form required for the records used in library operations. The purpose is to lay the basis for seeking general agreement on standards in the conversion of such information to machine-readable form. The National Science Foundation is itself supporting the American Institute of Physics in a programme directed towards improving the communication of scientific information. This will enable the Institute to continue its work on creating an adequate reference retrieval system for physicists, its collection of information from authors using the property–object–method scheme of analysis, and its investigation of the relations between cited and citing physics papers, including an investigation of the reasons why articles are cited. An experimental system which can use the data already collected will also be tested. Research is continuing at the Massachusetts Institute of Technology on the development of a realistic test environment for evaluating ideas and systems components capable of making the flow of scientific information more effective. The National Aeronautics and Space Administration has established an unusual search tape system which provides up-to-date comprehensive search capabilities at individual research centres of the Administration's entire collection of reports.

The Sarawak Museum

THE latest issue of the *Sarawak Museum Journal* (11, Nos. 21–22 (New Series); July–December 1963) maintains the essential regional character of this publication. Mrs. Barbara Harrisson records some interesting experiments in educating orphan young orang-utans for normal life in the jungle, and the editor, Mr. Tom Harrisson, has several papers on local natural history. Additional information regarding the animal bones found in Niah Cave are given by Lord Medway and the Earl of Cranbrook. In all, there is a total of 31 interesting and well-illustrated papers.

South Australian Museum

THE report of the South Australian Museum for the year ended June 30, 1963 (Pp. 14 + 1 plate. Adelaide: Government Printer, 1964), is the first issued under the directorship of Dr. W. P. Crowcroft, and records the continued anxiety regarding accommodation. The installation of a mezzanine floor in the Stirling Gallery provided an extra 1,500 ft.^{2} for storage. Several collecting projects were undertaken during the year, with the view of acquiring detailed field observations in support of material collected for research purposes, and the recording of the destruction of native habitats. Trips were thus undertaken to the Gulf of Carpentaria, the Simpson Desert, and Sturt's Stony Desert. Some of the records of this work are indicated in an impressive list of publications by the staff.

Physics Conference, Gothenberg

THE twelfth General Physics Conference arranged by the Swedish National Committee for Physics was held in the Chalmers Institute of Technology, Gothenberg, during June 4–7, 1963. The attendance of some 300 members, and particularly the large number of contributed papers, required the meetings to be held in three parallel sessions in adjacent lecture halls. One general lecture was given each day by an invited speaker. Prof. D. Amati (CERN) spoke on the present situation in the high-energy theory; Dr. J. J. Quinn (Radio Corporation of America) on the properties of a quantum plasma in a uniform magnetic field; Prof. G. Ekspong (Stockholm) on experimental results concerning elementary particles; and Dr. T. Ericson (CERN) on some statistical phenomena in nuclei. The members were entertained to a dinner and dance by the city council on the evening of June 6, and demonstrations were arranged in the physics and electrical engineering departments of the Institute. A brief report of the proceedings of the Conference, together with summaries of the papers presented, is given in *Arkiv for Physik*, 26, 233 (May 22, 1964).

American Society of Plant Physiologists

THE American Society of Plant Physiologists has announced the following awards: *Stephen Hales Prize*, to Prof. F. C. Steward, Cornell University, New York, in recognition of his work on the salt uptake of plants and the nitrogenous constituents of plant tissues, and his investigations of growth substances; *Charles F. Kettering Award*, to Dr. L. N. M. Duysens, University of Leiden, in recognition of his contributions to photosynthetic research; *Charles Reid Barnes Life Membership Award*, to Prof. W. Z. Hassid, University of California at Berkeley, in recognition of his work in the field of sugar biochemistry which has led to discoveries in the metabolism of carbohydrate compounds. Charles A. Shull Life Membership Certificates have been presented to the following members, who were present at the founding of the Society and have retained their interest in its activities: Prof. C. H. Arndt, Clemson College, South Carolina; Prof. W. M. Atwood, Oregon State University; Prof. A. L. Bakke, Iowa State University; Prof. J. P. Bennett, University of California; Dr. W. B. Davis, U.S. Department of Agriculture; Dr. R. B. Dustman, University of West Virginia; Dr. F. M. Eaton, University of California; Prof. G. R. Johnstone, University of South California; Dr. J. P. Jones, U.S. Department of Agriculture; Prof. A. E. Murneek, University of Missouri; Prof. A. C. Saeger, University of Kansas City.

The following were elected officers of the Society: Dr. S. Aronoff, U.S. National Science Foundation (president); Prof. G. G. Laties, University of California (vice-president); Prof. H. Beevers, Purdue University, Indiana (member of the executive committee); Prof. W. D. Bonner, jun., University of Pennsylvania, and Prof. P. J. Kramer, Duke University, North Carolina (members of the editorial board of *Plant Physiology*). These elections will take effect from October 1.

The Night Sky in October

NEW moon occurs on Oct. 5d 16h 20m U.T. and full moon on Oct. 21d 04h 46m. The following conjunctions with the Moon occur: Oct. 1d 00h, Mars 2° S.; Oct. 2d 03h, Venus 5° S.; Oct. 16d 18h, Saturn 3° N.; Oct. 22d 23h, Jupiter 1° N.; Oct. 29d 09h, Mars 3° S.; Oct. 31d 23h, Venus 4° S. Venus is in conjunction with Regulus on Oct. 5d 07h, Venus being 0·4° S. Mercury is too close to the Sun for observation. Venus is a morning star, rising at 2h 00m, 2h 35m and 3h 15m on October 1, 15 and 31, respectively. Its stellar magnitude is −3·6; its distance from the Earth increases during the month from 89 to 108 million miles and the visible portion of the apparent disk from 0·654 to 0·765. Mars rises at 0h 20m, 0h 15m and 0h 05m at the beginning, middle and end of the month, respectively. Its stellar magnitude is +1·5 and its distance from the Earth on October 15 is 165 million miles. Mars is in Cancer until October 14, when it passes into Leo. Jupiter rises at 19h 10m, 18h 10 m and 17h 05m on October 1, 15 and 31, respectively. It is now moving westwards near the boundary between Aries and Taurus, its stellar magnitude is −2·4 and its distance from the Earth on October 15 is 384 million miles. Saturn sets at 2h 15m, 1h 20m and 0h 20m at the beginning, middle and end of the month, respectively. It is in Aquarius, moving westwards among the stars. Its stellar magnitude is +0·8 and its distance from the Earth on October 15 is 850 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Oct. 13d 18h 34·0m, 51 Sgr. (*D*); Oct. 13d 19h 06·3m, 52 Sgr. (*D*); Oct. 19d 01h 41·2m, 30 Psc. (*D*); Oct. 28d 01h 22·6m, γ Cnc. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Orionid meteors are active during October 15–25, with maximum on October 21, but conditions for observation are unfavourable.

Announcements

PROF. ALEXANDER WEINSTEIN, of the University of Maryland Institute for Fluid Dynamics and Applied Mathematics, has been elected a foreign member of the Accademia Nazionale dei Lincei, Rome. Prof. Weinstein is well known for his outstanding contributions to applied mathematics, especially to the theory of partial differential equations and the calculation of vibrations.

THE 1964 symposium of the Technicon Instruments Company, Ltd., on "Automation in Analytical Chemistry" will be held in London during October 12–14. Further information can be obtained from Technicon Instruments Co., Ltd., Hanworth Lane, Chertsey, Surrey.

THE twenty-seventh annual meeting of the American Documentation Institute on "The Parameters of Information Science" will be held in Philadelphia during October 4–8. Further information can be obtained from A. W. Speakman, E. I. du Pont de Nemours and Co., Wilmington, Delaware.

AN international symposium on "Laser-Physics and Applications" will be held in the University of Berne during October 12–14. Further information can be obtained from R. Dändliker, Institut für Angewandte Physik, Universität Bern, Sidlerstrasse 5, Bern.

THE annual conference of the British Association for Commercial and Industrial Education on "Policy in Perspective" will be held in the University of Nottingham during September 24–26. Further information can be obtained from the Conference Secretary, British Association for Commercial and Industrial Education, 26A Buckingham Palace Road, S.W.1.

A SYMPOSIUM on "Relation of Measurements of Radioactive Contamination in the Working Environment to Personal Exposure", arranged by the Society for Radiological Protection in association with the Joint Health Physics Committee, will be held in the Manchester College of Science and Technology on October 7. Further information can be obtained from Mr. E. T. Wray, Radiological Protection Division, U.K. Atomic Energy Authority, Harwell, Didcot, Berks.

THE annual meeting of the Conference on Electrical Insulation of the Division of Engineering and Industrial Research, National Academy of Sciences—National Research Council, will be held in Cleveland, Ohio, during October 12–14. Further information can be obtained from D. W. Thornhill, Conference on Electrical Insulation, National Academy of Sciences—National Research Council, 2101 Constitution Avenue, Washington 25, D.C.

THE national conference of the Institute of Personnel Management on "Economic Growth and Human Resources" will be held in Harrogate during October 9–11. In conjunction with the conference, five one-day courses will be held on October 9 on: evaluation and development of the personnel function; organization and staffing; staff assessment and counselling; improving selection techniques; training as an aspect of personnel management. Further information can be obtained from the Institute of Personnel Management, Management House, 80 Fetter Lane, London, E.C.4.

SCIENTIFIC AND ENGINEERING MANPOWER IN THE UNITED STATES

THE report of the Committee on the Utilization of Scientific and Engineering Manpower in the United States*, which is discussed on p. 1101 of this issue of *Nature*, bases its recommendations and conclusions largely on the facts set forth in the second chapter of Part 1 of the report, "Needs and Resources". Between 1940 and 1960, the proportion of scientists and engineers in the working population greatly increased, and now, at 1·7 million, exceeds 2 per cent. Of this total, about 950,000 are engineers, 500,000 scientists and 250,000 teachers of science or mathematics at the secondary school level. By 1970, the total is expected to reach 2·8 per cent of the working population. About 40 per cent are engaged in private industry or commerce, 20 per cent in education, and between 20 and 30 per cent in work affecting national security and its position in the exploration of space. No major division of science includes more than 7·5 per cent of the scientists and no branch of engineering more than 15 per cent of engineers. Of those with doctorates, 29·2 per cent are scientists, 15·1 per cent being in the physical sciences and 7·4 per cent in the biological sciences. Secondary school teachers account for 14·7 per cent and engineers for 56·1 per cent; 6·7 per cent are psychologists or social scientists. Two out of three scientists and two out of five engineers are engaged in research and development. It is estimated that in 1963, of the total graduates in science and engineering, 57 per cent were employed in industry, 11 per cent by the Government, 12 per cent in colleges and universities and 15 per cent as secondary school teachers.

These figures and profiles are supported in Part 2 of the report by nine study papers. Mr. F. H. Harbison discusses measures towards the development of a comprehensive man-power policy; G. Colm and L. A. Lecht outline requirements for scientific and engineering man-power in the 1970's; and A. M. Ross considers how the United States uses its engineers and scientists. Proposals for development of an improved man-power-related information programme are detailed by A. O. Gamble, while P. W. Charington considers the impact of Government policy and action on the utilization of scientific and engineering man-power in the acquisition of weapons and space systems in a paper entitled "Systems-Acquisition and the Utilization of Scientific and Engineering Man-Power (Requirements and Programme-determination, Contracts and Grants)". In a further paper, he submits two case studies of the utilization of scientific and engineering man-power in the major military systems, *Titan II* and Naval Tactical Data Systems: this is summarized and its principal findings only are presented. In the last three papers, A. B. Kinzel presents an industrial view of the Government's impact on civilian research and development man-power, L. M. Hartman describes industrial practice affecting the utilization of scientific and engineering man-power, and R. H. Bolt takes a look ahead at man–machine partnership in intellectual pursuits.

---

* *Towards Better Utilization of Scientific and Engineering Talent: a Program for Action.* Report of the Committee on Utilization of Scientific and Engineering Manpower. Publication No. 1191, National Academy of Sciences. (Printing and Publishing Offices, National Academy of Sciences, Washington, D.C., 1964.)

FILM AND TELEVISION IN THE WORK OF THE UNIVERSITIES

A ONE-DAY conference on the film and television in the work of the universities was held at the Royal College of Art, London, on July 21. Mr. Michael Clarke, tutor in the Department of Television and Film at the College, deserves every praise and admiration for arranging the meeting. The interest and enthusiasm shown by his audience were a welcome indication that audio visual media may shortly emerge from their adolescence.

The British Universities Film Council conference at Senate House in March, 1963, set out to survey the field of closed-circuit television within institutions of higher education from the severely practical point of view of application, technique, instrumentation and cost. At the Royal College of Art, Members of Parliament, university vice-chancellors and professors, members of the University Grants Committee Sub-committee on Audio Visual Aids Facilities in Higher Education, directors and senior executives of the independent television companies and of the B.B.C., as well as a catholic selection of experts in the arts and sciences came together to hear and to discuss a wide-ranging and more general search for the present and future role of film and television in the universities.

In opening the morning's session on "Potential Functions of Film and Television in Higher Education", Mr. Clarke pointed out that the meeting was too large to achieve any concrete results and that the main aim should be to gain information from each other. The Television and Film Department within the Royal College of Art would accept up to ten students a year who had completed their art-school training. They would go through a three-year course on film and closed-circuit television to learn how to think in terms of moving pictures. From among these students, it was hoped, would come some of the producers and directors of the future. A one-year course exists for those who are already in industry but wish to experiment or enlarge their knowledge. The nucleus of an academic film unit has been created and has started to make teaching films in collaboration with Imperial College of Science and Technology, London.

Mr. Clarke claimed that film and television should be regarded as modes of communication in their own right. If they were to be fully exploited in this way, both users and producers would have to rethink and learn how to use visual concepts. This should apply not only to the professionals but also to the teachers; all should learn to think in terms of illustration.

Prof. Collin Cherry, Department of Telecommunication, Imperial College, and author of *On Human Communication* (John Wiley and Sons and Science Editions, Inc., 1961), spoke on his experimental use of simple closed-circuit television equipment as an enlarging device during his lectures on engineering, where this device enabled him to use small models to illustrate abstract concepts. He also recorded a twenty-minute summary immediately after each lecture, so that his students could listen to the tape-recording either to supplement their notes or to catch up on a lecture they might have missed.

Prof. Cherry emphasized that the academic lecture should impart a basic understanding and interest in the subject, not detailed information. He expressed the hope that television would cut its traditional cinema apron strings and make greater use of its essentially electronic genes. Future use of television in the lecture theatre might bring outside events and phenomena to the student to enrich his understanding and visual experience. A great expansion could be envisaged as soon as the restricted availability of wave-lengths had been overcome.

As a complete contrast, Mr. Edgar Anstey of British Transport Films and vice-president of the International Scientific Film Association recalled that Percy Smith produced superb classroom films on biological subjects almost fifty years ago. While films had been produced ever since, lamentably little effective use had been made of them. This might possibly be explained by the lack of appreciation of their enormous potential and, particularly, by the ignorance of the film language and its ability to appeal not only to logic but also to the emotions.

Prof. David Daiches, Department of English, University of Sussex, recounted his experiences in mounting twelve experimental television broadcasts on English literature and how he attempted, and evidently most successfully, to impart a visual understanding of concepts which could not be explained by words alone. So, for example, he illustrated the concept of stylization by showing a photograph of a real lion followed by a drawing of a heraldic lion. This demonstration was followed by the reading of poems on Nature, some realistic recounts of what the poet had seen, others giving a stylized account of another poet's experiences. As a further example, Prof. Daiches mentioned the film of Dublin streets which was used as background illustration to the reading of part of Joyce's *Dubliners*.

Prof. Eric Crook, Department of Biochemistry and Chemistry, St. Bartholomew's Hospital Medical College, London, brought the meeting back from open broadcasting to the uses of television and film within the university. He outlined the vocational rather than academic nature of the medical curriculum and how his college was revising the sequence and manner of teaching the preclinical course. He emphasized that an effort should be made to exploit the visual aspects of the material to be learned, in order to help the student who was very largely visually orientated in his method of learning and retention of knowledge.

Mr. Peter Laslett, Trinity College, Cambridge, bridged the transition from the morning to the afternoon session on "Immediate Problems and Needs" with his account of the "Dawn University" experimental broadcasts from Cambridge and the television links between Cambridge and Norwich, and Cambridge and Imperial College, London. Mr. Laslett felt that few students would be able to proceed to a degree examination unless they were given a great deal of other help and guidance, and that the main bulk of the viewers would merely look for a "cultural uplift".

While such broadcasts could well train or retrain mothers who wanted to go back to teaching, a degree course of the air would require a new central national body. Television teaching could not be cheap. At an estimated cost of £2,000 per hour a degree course of 500–600 hours would cost £1,200,000; and yet every university offers not just one but many degree courses. To be effective each hour of television broadcasting would have to be accompanied by something like four hours of radio instruction, eight hours of correspondence course work and time when the students would actually visit the university to which they were attached.

Mr. Laslett made it clear that the subject was far too complex to be discussed satisfactorily in a short space of time. An organization had now been set up to discuss ways and means, and the University of Cambridge was prepared to mount a comparative experiment. Unfortunately, research into education did not appear to attract financial support, and no action could be taken at the present time.

Mr. S. Pitt Corder, Department of English, University of Leeds, gave a stimulating account of the important pioneering work now being translated into reality at his university. This University Television Centre will assist and stimulate the use of closed-circuit television as a visual aid and as a tool in research at department level. The central organization will develop television as a medium of teaching in its own right, and central studio facilities have been created for the distribution of instructional material to departments of the university. The Centre will also institute its own researches into educational television.

The staff is planned to provide a small team to advise on departmental uses and to offer a loan and repair service. Central activities will be carried out by a bigger team equipped with high-quality apparatus. The director, who will have an academic background, will probably be supported by a studio manager-producer, an assistant producer, two technicians, an art director and assistants, clerks, drivers and handymen to form a team of some ten to fourteen people. Naturally the Centre will wish to lean quite heavily on existing university film and photographic facilities. It may not prove easy to find suitably qualified and experienced personnel, and it is interesting to note that school teachers have already asked to be trained, so that they may be enabled to use television in their schools.

Mr. Thorold Dickinson, Slade School of Fine Art, University College, London, joined the discussion at this point to direct attention to the American and Russian trend towards smaller and more portable film cameras for more flexible documentary and dramatic recording. He advanced the argument that this would make filming rather less the preserve of the professional and that the teacher could acquire the necessary expertise within a short period of two to three months, and that this might apply equally to the use of television.

As a partial reply to the problem of selection, storage and availability of films and television recordings (video tapes), raised by Mrs. Eirene White, M.P., Mr. Dickinson pointed to the enormous amount of documentary film material stored by the various television companies. He had been able to obtain some interesting and valuable examples from the United States and from France on condition that these films remained under his supervision. Even with this safeguard of copyright it had not yet proved possible to secure the same facilities from British companies.

Mr. R. Postgate, deputy controller of educational broadcasting, B.B.C., gave a survey of the Corporation's past, present and future policy. He stated that it had always been thought desirable to appoint members of the teaching profession to lead educational broadcasting policy. Apart from the educational activities which were already well known, the Corporation was planning to use its second television channel during the day-time for educational programmes as soon as the channel had achieved wider coverage. Some twenty-four broadcasts were planned to assist those who were working for the social economics diploma of the University of London. On the whole, however, it was the policy of the B.B.C. to think in terms of a national service, and the main emphasis had to be on schools because of the extreme shortage of teachers.

Mrs. Mary Adams of the Television Viewers Council and the Mental Health Film Council made a strong plea for a national education television channel. She defended the point of view that schools and universities should formulate the purpose, nature and contents of educational broadcasting, instead of leaving the initiative to the broadcasting companies. Mrs. Adams proposed that an information centre be created, and that a fellowship might be financed to prepare a survey of present activities in instructional television.

The chairman, Sir John Newsom, chairman of the I.T.A. Education Council, in summing up the discussion, proposed that a further meeting be called early in the new year to concentrate on more specific topics. In the meantime, the conference on the use of film in teaching and research, to be held at the University of Birmingham in September, will serve as a further stimulus.

The conference at the Royal College of Art proved to be a useful forum for the exchange of information and opinion. The next meeting may accept the view expressed by a number of discussion speakers that film and television should not be considered in isolation but in the wider context of all methods of learning and of teaching. Almost invariably the appropriate use of several methods in combination will produce the best results.

While film and television can be expressions of art in their own right, the primary usefulness will probably be as aids in communication. The selection of the most effective methods of communication presupposes a clear understanding of the end product, what the student is supposed to be able to do, and how he is expected to think and react at the end of his course of studies. An appreciation of the teaching situation and the context in which learning is to take place will be just as important. Furthermore the producer of audio visual aids should base his planning on a clear definition of objectives, on existing knowledge of the proposed audience, and on the purpose of the contents. Finally, students should be given an opportunity to learn how to learn from visual information. Visual literacy, a concept cited by Sir Arthur Elton, is essential for the effective construction, use and acceptance of information in visual terms by producers, teachers and students respectively. The literature on the effective construction and use of audio visual teaching devices, both for mass instruction and for individual learning, as well as the literature on methods of testing, is considerable and should be made more widely available. It is, therefore, a pleasure to learn that Lord Robbins will be concerned with a new journal on the technology of education, *New Education*, which is to commence publication in November of this year.

OXFORD CHROMOSOME CONFERENCE

AN international conference on chromosomes, attended by more than a hundred delegates from twenty countries, was held at Magdalen College and the Botany School, University of Oxford, during July 28–31. The deliberations of the conference were of five kinds: dissertations, demonstrations, business meetings, social functions, and extra-mural informal gatherings.

The proceedings began with an address of welcome by Prof. C. D. Darlington in which he recalled for the conference the content of Weismann's classic paper published in *Nature* (36, 607; 1887). This he saw as still a charter for those who examine chromosomes.

Thirty other papers were delivered in four sessions. The first, on plants, included a report by Prof. A. Müntzing (Sweden) on accessory (*B*) chromosomes in *Poa* and *Secale*. The latter was also the subject of an investigation by Dr. J. Sybenga (Netherlands) on the possible role of interchanges in determining selective pairing in polysomics. Preferential autosyndesis was not observed, indicating that interstitial changes in homology have no detectable effect on pairing which is localized near the ends. The control of pairing was considered also by Dr. R. Riley (Great Britain), who described work on wheat undertaken jointly with Dr. E. R. Sears (U.S.A.). It revealed a genetic condition which determined asynapsis but only under certain temperature conditions. Other polyploids were the subject of papers by C. J. Marchant (Great Britain) and Prof. J. K. Morton (Sierra Leone). A different aspect of chromosome mechanics, diplotene repulsion, was discussed by Dr. K. Pusa (Finland), who concluded that such a force exists. The chairman of this session was Dr. E. R. Sears and it also contained a paper by Mrs. E. R. Sansome (Nigeria), who presented evidence in favour of the diploid condition of the vegetative phase in the Oömycetes.

The second session was concerned with the structure of the nucleus and with chromosome abnormalities induced by mutagens. Prof. Müntzing acted as the chairman of this session, which included papers by Dr. H. Ris (U.S.A.) and L. F. La Cour (Great Britain), who considered chromosome organization as revealed by the electron microscope and nucleolar structure respectively. There were accounts also by Drs. H-G. Keyl (Western Germany) and B. A. Kihlman (Sweden), who discussed various aspects of DNA synthesis. Papers by Dr. R. C. von Borstel (U.S.A.) and Dr. G. R. Lane (Great Britain) reported investigations on X-ray chromosome breakage while Mr. C. J. Grant (France) discussed the delay in mitosis caused by chemical mutagens. This session included a report by Prof. G. Östergren (Sweden) on the effects on chromosome behaviour of induced point mutations, and he gave a demonstration on the same subject. Of special importance were his observations of chromosomes which entered pollen grain mitosis although they had not divided into chromatids.

Insects and mammals were the subject of the third session, which was chaired by Prof. H. Bauer (Western Germany). It began with a beautiful film of meiosis in *Pales* by Dr. R. Dietz (Western Germany), who also exhibited three other films at a supernumerary session held on the last day of the conference. These showed that the spindle could function in a normal way even in the absence of centrioles and they threw considerable light on the mechanical behaviour of the hereditary sex univalents of this genus. Other aspects of chromosome movement and their control were described by Dr. I. Geyer-Duszýnska (Poland), while the effects of α-heterochromatin on crossing-over were considered by Dr. B. E. Wolf (Western Germany). Gene action in *Drosophila* was the subject of two papers, one by Dr. O. Hess (Western Germany) and the other by Dr. H. D. Berendes (The Netherlands). Chromosome polymorphism in black-flies was considered from the taxonomic point of view by Dr. R. W. Dunbar (Great Britain), who also gave a demonstration, while intra-specific chromosome variation of the Robertsonian type was discussed by Dr. C. E. Ford (Great Britain) and Dr. J. Wahrman (Israel).

Prof. E. Battaglia (Italy) was the chairman of the final session which contained papers dealing with mammals and the recent, far-reaching, discoveries in man. Putative Robertsonian-type variation in humans was described by Dr. J. L. Hamerton (Great Britain), but there was a suggestion that the condition was better regarded as a monosomic one following unequal interchange between acrocentric chromosomes. Dr. M. Fraccaro (Italy) considered the occurrence of iso-chromosomes and deficiencies in the long arm of the X-chromosome in the same species. Attempts to identify the chromosomes of man individually by different methods were discussed by Dr. D. T. Hughes (Great Britain) and by Dr. C. H. Ockey (Great Britain), who supported his paper with a demonstration. Miss U. Mittwoch (Great Britain) reviewed the problem of the Barr-bodies in human females. This session also contained a very interesting account by Dr. S. Ohno (U.S.A.), who described a hitherto unique condition in mammals, namely, an *XO* soma as the normal state in females of the creeping vole. It is associated with mechanisms leading to the formation of only *X*-carrying eggs and *Y*- or *O*-containing sperm.

The thirty demonstrations included thirteen by members of the host department. They covered a wide range of organisms from microbes to man and a variety of techniques including experimental breeding, autoradiography and electron microscopy. Giant models of meiosis made at the Botany School were exhibited. The spiral structure of chromosomes was demonstrated on closed-circuit television by Mr. Canio Vosa (Italy), now of the Botany School, Oxford, and visits to the Genetic Garden of this School were conducted by Prof. Darlington and Mr. Kenneth Burras, the superintendent of the Botanic Garden. This garden contains a collection of variegated plants, chimæras and chromosomally interesting plants used principally for teaching purposes.

These activities, the demonstrations and the papers, served the immediate purpose of the conference which was the exchange of information and ideas. Chromosome investigations have had a tremendous impact on all branches of biology, especially in recent years, and they have established connexions with medicine, agriculture, sociology (anthropology) and the physical sciences. But the extension and expansion of this technique have led to the unforeseen dispersion of chromosome workers themselves and reduced communication between them. Enquiries, beginning at Oxford, had suggested that the need for greater contact could best be fulfilled by regular meetings organized by an international body. With this in view, the chairmen of the four sessions were asked to function as a steering committee and they gave their recommendations at the business meetings.

It was decided that they, by co-option, should increase their number to nine with Dr. K. R. Lewis (Great Britain) as secretary and that this body should serve as an international committee responsible for the second conference of this kind which will be held in Oxford in 1966. At that conference the members of the original steering committee should be replaced by members elected by the conference. Such elected members would then be responsible for the organization of later international conferences every two years. The committee would, by rules or example, indicate the form of future conferences and suggest other activities by which chromosome investigations could be advanced.

The spirit of this first conference indicated a vigorous future for this new venture and anyone interested in it is asked to communicate with me (Botany School, Oxford). The full proceedings of the conference will be published as a supplement to *Heredity*.

K. R. LEWIS

SPECTRAL EVIDENCE ON THE ORIGIN OF TYPE I SOLAR RADIO STORMS AND THE CORONAL MAGNETIC FIELD

By J. P. WILD
C.S.I.R.O. Radiophysics Laboratory, Sydney, Australia
AND
A. TLAMICHA
Astronomical Institute, Czeskoslovakian Academy of Science, Ondřejov

THE dynamic spectrum of metre-wave radiation emitted by the Sun during type I storms[1,2] consists of a conglomeration of storm bursts which are scattered in the time-frequency plane over periods of hours or days and within frequency bands of tens or hundreds of megacycles per second. Owing to the complexity and lack of systematic features in the macroscopic disposition of these bursts, spectrographic investigations have yielded no real clues about the physical nature of the storms as a whole. The purpose of this article is to direct attention to a particular class of systematic macroscopic feature which we have found to be repeatedly evident on the spectral records taken at Dapto, New South Wales, during the last solar cycle. The feature in question is the occurrence of bursts grouped together in tens or hundreds to form narrow-band 'chains' with durations of the order of 1 min or several min and band-widths of the order of 10 Mc/s. An isolated example of this phenomenon was briefly reported some years ago[3].

The characteristics of the type I burst-chains are illustrated by the examples given in Figs. 1 and 2 and the left-hand columns of Table 1; many more examples can be found in the records and indeed it is our subjective impression that the majority of type I radiation may be resolved into chains. The chains may apparently occur in any part of the metre-wave spectrum (30–300 Mc/s) and may drift systematically in frequency at a rate given by $\frac{1}{f}\left|\frac{df}{dt}\right| \lesssim 0{\cdot}1$ per min, the average rate being about half that for type II bursts. Although instances have been found in which the drift is positive (that is, from low to high frequency), the predominant drift is negative as in type II bursts. The chains may occur insignificantly among other complex storm activity, but sometimes dominate the record for periods of up to 1 h in which a sequence of chains with negative drift follow one another (Fig. 1*b*). Measurements using the Dapto swept-frequency interferometer have shown that variations in position on the Sun's disk of several minutes of arc may accompany the drift in frequency.

It is common, as in the lower record of Fig. 2, to find a pair of chains running roughly (but not exactly) parallel to one another at different frequencies, providing an example of the split-band phenomenon described by Elgaroy[2]. It is not clear whether this circumstance is always due to two independent sources simultaneously

Table 1. OBSERVED AND DERIVED CHARACTERISTICS OF CHAINS OF TYPE I BURSTS

Date	U.T.	Drift in frequency (Mc/s)	Duration (min)	Movement in height (10^5 km)	Upward velocity (km/sec)	*H* (gauss)
April 27, 1953	0018	210 → 185	1·7	0·9 → 1·15	250	2·5
	0038	230 → 180	4·8	0·7 → 1·2	160	1·6
	0045	178 → 161	2·7	1·2 → 1·4	120	1·0
August 12, 1957	0223	56 → 48	4·2	4·3 → 4·9	240	0·6
	0229	50 → 44	3·4	4·75 → 5·3	260	0·6
	0239	55·5 → 48	4·1	4·4 → 4·9	260	0·7
	0449	63 → 58	1·8	3·9 → 4·2	270	0·8
	0458	58 → 51	2·0	4·2 → 4·7	410	1·1
	0512	48 → 44	5·5	4·9 → 5·3	110	0·25
	0514	61·5 → 60	2·1	4·0 → 4·1	65	0·2
March 29, 1960	0602	47·5 → 45·5	0·8	5·0 → 5·15	380	0·9
		53 → 51·5	0·4	4·5 → 4·65	500	1·3
	0610	58 → 52	1·9	4·2 → 4·6	360	1·0
	2345	48 → 42	2·1	4·9 → 5·5	460	1·0
	2352	56 → 44	2·0	4·3 → 5·3	800	2·0

The heights and velocities are derived assuming the radiation to originate at the plasma levels determined from Newkirk's model of the solar atmosphere above an active region. The column *H* gives the radial component of the magnetic field derived from the assumption that the velocity is equal to the speed of Alfvén waves.

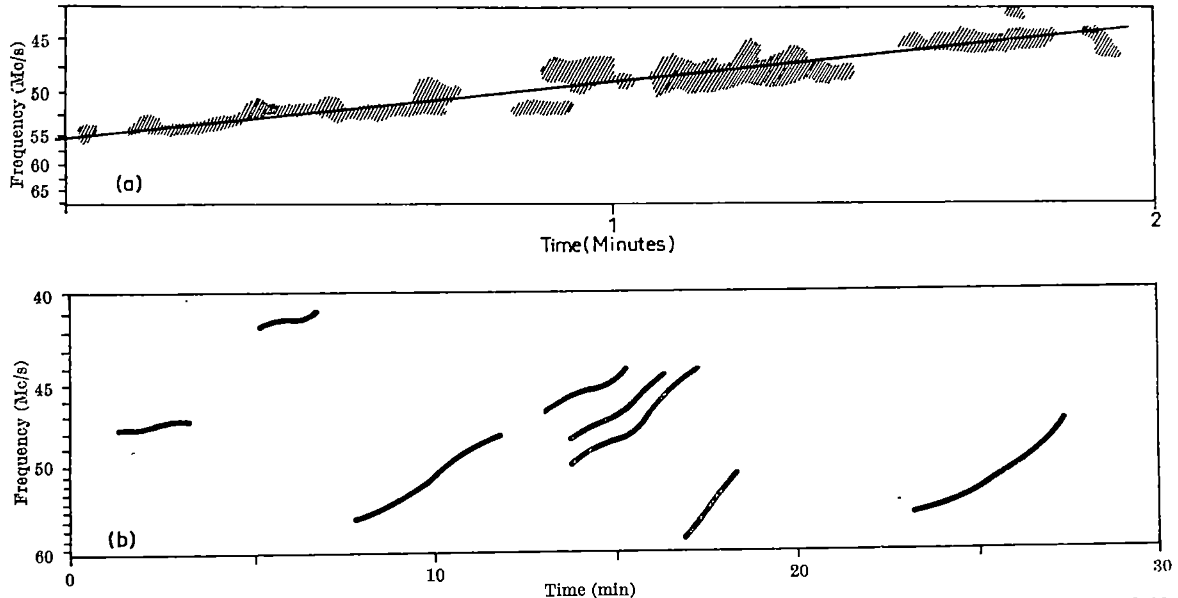

Fig. 1. Tracings of dynamic spectra. (*a*) An individual burst chain, the hatched areas indicating concentrations of type I bursts (March 29, 1960, 2352–4 U.T.); (*b*) several chains occurring in succession (August 12, 1960, 0215–0245 U.T.)

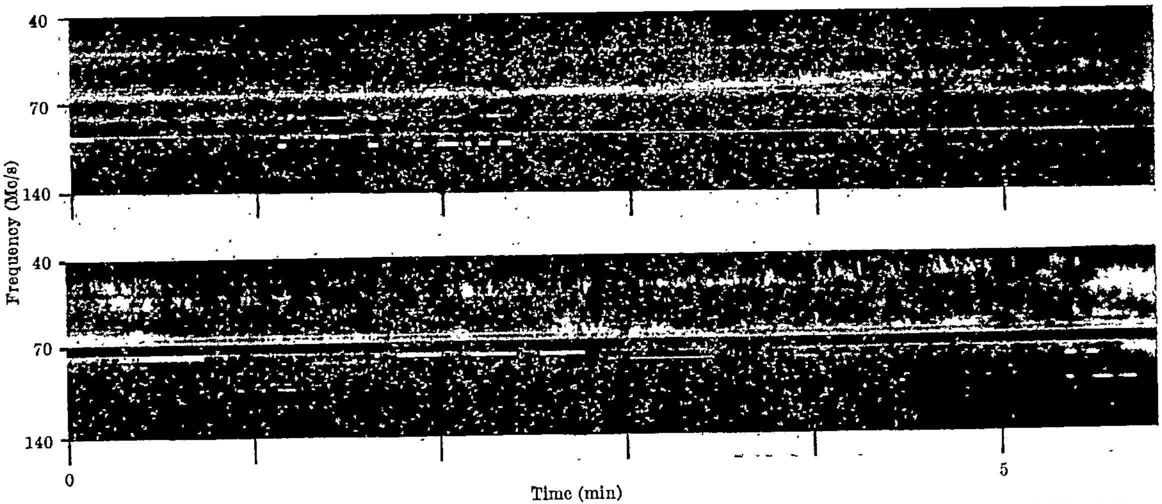

Fig. 2. Dynamic spectra of type I burst chains, showing examples of a simple and a double event (August 12, 1957, 0238–0244 and 0512–0518 U.T.)

present or whether it may sometimes be due to the excitation of two frequencies by the same source : there is often complete lack of detailed correspondence between the two bands though sometimes simultaneous brightness variations repeatedly occur in the two; the latter condition need not necessarily imply a common source but could be due, for example, to two independent sources linked by a fluctuating electron stream or magnetic field. Differences in position between two bands of a pair of up to several minutes of arc have been found.

We suggest that the two most important characteristics of type I chains—their narrow-bandedness and their frequency drift—could be due to either (*a*) effects of propagation limiting and varying the frequency range of emission from a relatively large, broad-band source, or (*b*) the motion of a localized source passing through regions of different electron density or magnetic field. Bearing in mind the preponderance of frequency drift in the one sense (negative) we strongly favour the latter. Other evidence and the majority of present theories support the view that type I bursts are generated by plasma oscillations in which the frequency is determined by the local plasma frequency ; and on this basis, the typical chain originates in a localized source moving upwards through the solar atmosphere. This hypothesis has been used in Table 1 to determine the heights and speeds of the events listed, for which purpose the plasma frequency is assumed to be determined by Newkirk's model of the solar atmosphere above an active region; the gyro-frequency has been assumed negligible in comparison with the plasma frequency. The sources are seen to rise through a height range of up to 10^5 km at speeds of several hundred km/sec, and to be capable of existing at heights of up to some 5×10^5 km.

The deduced velocities are too small to be identified with electron streams, since they are less than the speed of thermal electrons, and they are generally in excess of the field-free velocity of sound in the corona by a factor of between 1 and 5. We suggest that their most likely identity is that of a magnetohydrodynamic wave or shock wave, and that the evidence implies that some features, at least, of type I storms originate in such waves occurring in succession with predominantly ascending motion. The finding of any detailed optical correlation with these features would clearly be valuable, and we suggest that blue-shifted *H*α observations made with the necessarily high spatial and time resolution would provide the most likely chances of success.

It is important to distinguish between the phenomenon reported here and the type II burst : the latter also exhibits slowly drifting features and again is believed to originate in a magnetohydrodynamic shock wave. The distinction between the two phenomena lies in (i) the much greater magnitude and isolation of the type II events (which are associated with outstanding flares), (ii) the strong circular polarization of the type I (absent in the II), (iii) the much greater fluctuation (burstiness) of the type I, and (iv) the generally higher velocity of the type II. There thus appears to be a clear distinction in the generating mechanisms of the two. If our interpretation is correct, one may ask what causes a magnetohydrodynamic wave or shock wave sometimes to generate type I radiation and at other times type II. We suggest two possible distinctions : first the nature of the wave itself, whether it be transverse (Alfvén) or longitudinal (quasi-acoustic) and whether it be a linear disturbance or a shock wave ; and secondly whether or not the kinetic energy of the disturbance exceeds the magnetic energy in the region of the source.

If it is assumed that the disturbances responsible for the type I chains travel at the speed of Alfvén waves, which is given in terms of the magnetic field (H gauss) and plasma frequency (f_p Mc/s) by:

$$v \approx 2 \times 10^4 \, (H/f_p) \text{ km/sec}$$

then one is able to derive a value for the radial component of the coronal magnetic field. Such values are given in the last column of Table 1 and are seen to range from 1–2·5 gauss for heights near 10^5 km and mainly from 0·2–1 gauss for heights near 5×10^5 km. If the disturbances are actual Alfvén waves, these derived velocities are formally appropriate; if they are any other kind of magnetohydrodynamic wave or shock wave (other than a purely acoustic shock wave travelling along the field), the derived values represent upper limits to the magnetic field.

The detailed process of radio-wave generation is not considered here. It is interesting to note, however, that Takakura[4] has proposed a theory of type I bursts in which the radiation is attributed to plasma waves excited by superthermal electrons which are accelerated between two packets of Alfvén waves travelling in opposite directions. In terms of this theory a chain of type I bursts might conceivably be attributed to encounters between a single, outward-moving wave packet and a series of inward-moving packets following one another in quick succession. The detailed process proposed by Takakura is not, however, qualitatively compatible with an application of this hypothesis to the present observations, since Takakura requires the Alfvén waves to travel at about the mean speed of thermal electrons (~7,000 km/sec in the corona) and hence the magnetic fields to be of very much greater intensity than those inferred above.

We thank Mr. K. V. Sheridan and other colleagues who have contributed towards the observational programme of Dapto field station and Mr. S. F. Smerd for helpful discussion. This work was carried out at the Radiophysics Laboratory, Sydney, while one of us (A. T.) was on leave of absence from Ondřejov Observatory during the tenure of a C.S.I.R.O. fellowship.

ANION ADSORPTION ON PLATINUM BY THE MULTIPULSE POTENTIO-DYNAMIC METHOD

By S. GILMAN

General Electric Research Laboratory, Schenectady, New York

ADSORPTION of anions on platinum has previously been investigated by a variety of non-voltammetric techniques. These methods, most commonly applied to platinized platinum, include: (1) observation of the effect of anion adsorption on hydrogen deposition[1-3]. (2) measurement of the electrode potential shift resulting on addition of the adsorbable ion to a solution of sulphuric or perchloric acids[4-6]; (3) measurement of the pH or conductivity change of a relatively small volume of liquid, caused by displacement of hydrogen ions from the ionic double layer by anions[7]; (4) direct determination by quantitative analysis of anions lost from solution[8]; (5) direct determination of anion surface concentration by means of radioactive tracers[9-11].

The results reported for any particular anion vary with surface preparation, pH, potential, etc. One fairly clear-cut conclusion is that the halide ions specifically adsorb, with the extent of adsorption increasing as one descends down the series to the higher atomic weights[12]. Perchlorate ion is assumed to adsorb very slightly or not at all.

Recently, Breiter[13] made measurements of the capacity of a smooth platinum wire in perchloric-hydrochloric acid solutions under the conditions of periodically varying potential. This method served to bring the electrode to a more reproducible surface state than was generally accomplished in the non-voltammetric measurements of his predecessors. One disadvantage of the method is the inability to assign quantitative interpretation to the measured capacities.

The purpose of work recorded here was to develop methods for the investigation of ion adsorption along the same lines as previously applied to carbon monoxide[14-16] and oxygen 'adsorption'[17]. A 'multipulse potentiodynamic' approach, for example, has the advantage, when successfully applied, of providing simple initial boundary conditions, and allowing for quantitative interpretation of data. Two anions of different nature were chosen for this investigation. Chloride is highly adsorbed and is an oxidizable ion. Phosphate is relatively slightly adsorbed and is non-oxidizable. The investigation resulted in development of the desired quantitative methods for measurement of anion adsorption. These methods permit, in principle, the measurement of kinetics of adsorption and desorption, and determination of equilibrium surface coverages as a function of potential.

The electronic equipment, glassware and electrodes have been described previously[14]. The working electrode was a length of C.P. platinum wire of 0·064 cm^2 geometric area. The saturation hydrogen surface coverage, Q_{SH}, determined as described previously[15], was 0·272 mcoul./cm^2, suggesting a roughness factor of approximately 1·3. Q_{SH} was not found to vary appreciably during the measurements, suggesting little or no etching of the electrode in the dilute hydrochloric acid solutions used, and under pulsed conditions. Solutions of hydrochloric acid and of phosphoric acid were prepared by addition of the analytical-reagent grade chemicals to a stock solution of 1 N analytical-reagent grade perchloric acid. All measurements were made in a thermostatic bath at 30° C. All potentials are referred to a reversible hydrogen electrode in 1 N perchloric acid.

The multipulse potentiodynamic method can be used to detect extremely small amounts of adsorbed anions if proper attention is directed toward the establishment of a reproducibly clean initial surface state. The criteria previously used for such an initial condition are con-

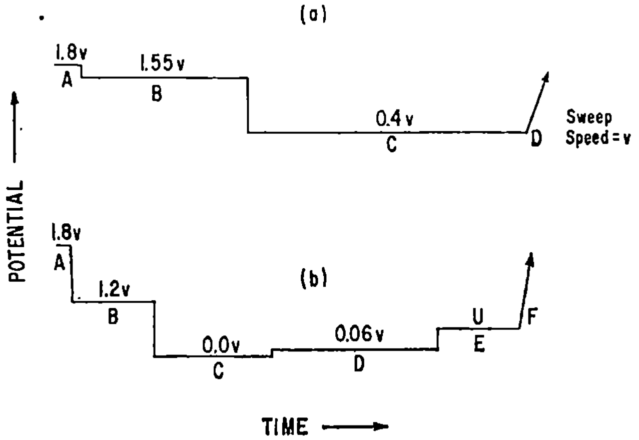

Fig. 1. Signal sequence applied to the working electrode

stancy of: (1) saturation hydrogen coverage, Q_{SH} (refs. 15, 17); (2) 'oxygen adsorption', Q_0 (refs. 15, 17); (3) differential electrode capacitance[17]. Sequence (*a*) of Fig. 1 consists of electrode pre-treatment steps *A* through *C* and measurement pulse *D*. The details and significance of each step have been described previously[15]. Steps *A* and *B* serve to cleanse the surface. During step *C*, the surface is reduced and adsorbable materials in the solution, including impurities, may be adsorbed. The presence of adsorbates on the surface after any period of time T_C at step *C* may be detected by examination of the 'oxygen adsorption' trace obtained on application of linear anodic pulse *D* (refs. 15–17). If a linear cathodic pulse is substituted for *D*, the resulting 'hydrogen adsorption' trace serves as an indication of surface cleanliness[15,17]. Both these criteria reveal a reproducible surface state for 10 msec $< T_C \leqq 10$ sec if a 1 *N* solution of analytical-reagent grade perchloric acid is used as the electrolyte. Longer 'clean times' are possible if the electrolyte is purified[15]. Sequence (*b*) of Fig. 1 is a modification of sequence *a* for use in 1 *N* perchloric acid containing hydrochloric acid. This modification is intended to reduce the extent of possible chlorine evolution and platinum dissolution during steps *A* and *B*. Steps *C* and *D* are chosen so that by the end of step *C* there are no chloride ions adsorbed on the surface and the concentration of molecular hydrogen in the adjacent solution is small. Steps *A* and *B* are of 2- and 15-sec duration, respectively. Step *C*, the purpose of which is to eliminate adsorbed anions, is of 2-min duration. Paddle-stirring of the electrolyte is continued from the beginning of step *A* to the end of the first 0·5 min of step *C*. By the end of step *C* the solution is quiescent, but the concentration of hydrogen near the surface is excessive. This is reduced to a tolerable level by application of step *D*, which is of 10-sec duration. If the value of *U* of step *E* is taken as 0·4 V and the perchloric acid solution contains no added adsorbable anion, the 'oxygen adsorption' trace measured by application of linear anodic sweep *F* is identical with that obtained by means of sequence (*a*), Fig. 1. If, on the other hand, the perchloric acid is made 10^{-3} *N* in hydrochloric acid, *U* is taken as 0·7 V and pulse *F* is set at $U = 1{,}000$ V/sec, the 'oxygen adsorption' trace varies gradually with time as indicated in Fig. 2. Trace 1 of Fig. 2 is the trace obtained in the absence of hydrochloric acid, under which conditions the same trace would be obtained for values of T_E over 10 sec. The difference in area (in mcoul.) between trace 1 and any other trace of Fig. 2 is the decrease in 'oxygen adsorption' (ΔQ_0) for that particular value of the adsorption time, T_E. A plot of ΔQ_0 versus $T_E^{\frac{1}{2}}$ results in excellent linearity. The particular slope obtained is precisely that predicted for the following conditions:

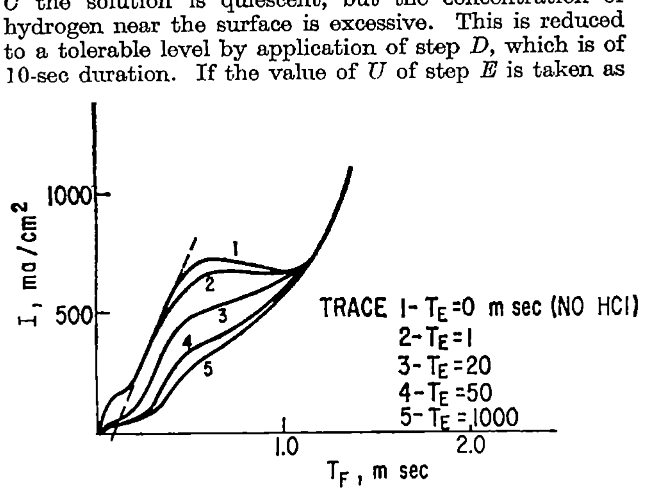

Fig. 2. 'Oxygen adsorption' traces obtained by means of signal sequence (*b*), Fig. 1. Electrolyte composition $= 10^{-3}$ *N* hydrochloric acid, 1 *N* perchloric acid

(1) The adsorption of one equivalent of chloride ions hinders the 'adsorption' of two equivalents of oxygen.

(2) Adsorption of chloride ions is controlled by semi-infinite linear diffusion for the short time required to reach maximum coverage.

(3) No reaction (for example, chlorine evolution, platinum dissolution) occurs at an appreciable rate compared with the rate of adsorption of chloride ions (for this particular concentration, and sweep speed, *v*). Condition 3 is made possible for any concentration of adsorbable anion by choosing *v* so that the duration of step *F* is small compared with the time required for the diffusion of an appreciable amount (compared with a monolayer) of the anion to the surface.

If step *E* is made sufficiently long, and *U* is taken as 0·7 V, the rate of adsorption of chloride ions eventually drops to zero when the amount of chloride is still smaller than a monolayer. This amount is an equilibrium value since it can be obtained by adsorbing chloride ions at 0·8 V, and allowing description to proceed to completion at 0·7 V. Equilibrium surface coverages may be measured for any value of *U* up to 0·8 V. The equilibrium surface coverage is approximately linear between 0·15 and 0·80 V. The equilibrium surface coverage at any fixed potential in this range appears to depend approximately on the log of concentration.

Observations on phosphate adsorption are similar to those for chloride, except that the equilibrium surface coverages are approximately 1/5 as large.

Additional observations suggest that adsorbed chloride is not oxidizable at any appreciable rate at potentials up to 1·6 V. This is probably related to the fact that the surface undergoes a valence change during adsorption (starting at a potential no higher than 0·7 V), resulting in a species having the stoichiometry (but not the structure) of $PtCl_2^-$. Evidence for this last statement is obtained by measuring the anodic current which flows during chloride adsorption at constant potential.

It is likely that the multipulse potentiodynamic method might be applied successfully to the quantitative examination of the adsorption of many different anions on platinum and other metals.

AN ANTIFOULING AND ANTI-CORROSION SYSTEM

By B. WISELY

C.S.I.R.O., Marine Laboratory, Cronulla, Sydney

THE growth of barnacles or other fouling organisms on the hulls of modern ships increases residual friction and leads to decreased travelling speeds. Although the speed losses involved are usually small (less than 2 knots), they can cause large increases in fuel consumption; Redfield and Hutchins[1] indicated that fouling on ships of 1,850–35,000 tons (standard displacement) might increase their fuel consumption by 35–50 per cent after 6 months in temperate waters or after 3 months in tropical waters. The method commonly used to reduce fouling is to apply an antifouling paint, containing cuprous oxide, which has a deterrent effect on the establishment of fouling growths. Unfortunately such paints can also accelerate hull corrosion. As the British Corrosion Committee pointed out more than 20 years ago[2], antifouling paint performance can be completely satisfactory only when the underlying anticorrosive paint prevents any corrosion of the hull surface. For best results the antifouling and anticorrosive systems need to be individually effective and mutually compatible.

The hull protection system proposed here, and now under trial, consists of a cuprous oxide antifouling paint of the soluble matrix type applied over a solventless epoxy resin anticorrosive layer. It is intended for use with a conventional cathodic protection system. Antifouling paints operating on the soluble matrix principle have been available for many years, but their potential has not been utilized fully, probably because of inadequacies in the underlying anticorrosive paints. The use of a solventless epoxy resin as a replacement for conventional anticorrosive paint systems is a new development.

Shipfouling and external underwater corrosion arise from endemic and interacting processes located in four basic strata which are referred to here as the larval, antifouling, anticorrosive and hull layers.

Although 374 shipfouling species have been listed[3], many of these are not important. Redfield and Deevy's tabulation of data[4] for 131 ships docked in northern hemisphere ports[5,6] and Skerman's analyses for 89 ships docked in the southern hemisphere[7] show clearly that the important fouling groups involved are acorn barnacles, bryozoans, tubeworms, hydroids, algae, bivalve molluscs and tunicates. The shipfouling problem is initiated by the larvæ of these organisms (or the equivalent stages in the algae) which have arrived at the hull surface and are attempting to attach to it. Antifouling methods should prevent this larval layer from colonizing the hull successfully and so avoid, from the beginning, the development of bulky adult fouling organisms on the hull.

The antifouling layer usually consists of a paint containing cuprous oxide as the toxic agent. Biological observations show that such paints can be effective against larvæ of four of the seven important fouling groups mentioned earlier. Wisely[8] suggested that a larva approaching an active antifouling paint faces several distinct possibilities: (1) it may be repelled and move away; (2) it may become moribund before it can attach properly; or (3) it may attach, commence metamorphosis into a young adult and become moribund at some stage during this process. The terms 'repellent', 'pre-attachment mortality' and 'post-attachment mortality' have been applied to these respective effects[9,10]. Recently, Crisp and Austin[11] showed that cyprids of the barnacles *Balanus balanoides* (L.) and *Elminius modestus* Darwin were killed during, or often after, metamorphosis when they attempted colonization of a cuprous oxide antifouling paint (post-attachment mortality). Pre-attachment mortality resulting from contact with similar paints has since been reported for larvæ of the bryozoans *Watersipora cucullata* (Busk)[8] and *Bugula neritina* L.[10] and for larvæ of the tubeworms *Spirorbis lamellosa* Lamarck and *S. convexis* Wisely[12]. A repellent effect has now been recorded for larvæ of the bivalve molluscs *Mytilus edulis planulatus* Lamarck and *Lasaea australis* Lamarck[9]. Comparable investigations have yet to be made on hydroid and tunicate larvæ, and on the equivalent stages of larger marine algae. However, representatives of these groups and of other less important groups are common in Sydney Harbour, where cuprous oxide paints have successfully prevented fouling for 1–2 years, so it can be assumed that such paints are also capable of preventing colonization by these remaining groups.

The value of cuprous oxide as an antifouling agent has been established from biological observations and practical experience. It has advantages not possessed by other toxic substances so far tested for this purpose. These include low cost, suitable solubility and stability, and safe-handling characteristics. Organic and other inorganic substances tested have not been as effective or have had other disadvantages. The solubilities of cupric oxide and cupric hydroxide are too low for them to be used in antifouling paints, whereas the solubility of mercuric oxide is excessively high[13]. Organic toxicants more active than cuprous oxide have been found[14,15], but the majority of these were unsatisfactory in paint films[16]; some of these are specific in their action; for example, DDT is toxic to barnacles but not to other groups[17,18]; other organic toxicants, for example, methyl mercuric chloride, are toxic to man as well as fouling organisms[19].

Experimental work has established[20] that cuprous oxide antifouling paints will prevent fouling so long as the copper ions continue to leach out at a rate greater than 10 $\mu g/cm^2/day$. The difficulty lies in maintaining a leaching rate safely, but not wastefully, above this value for long periods. Ferry and Ketchum[21] described the two main types of antifouling paints available in 1952. The continuous contact type has a high cuprous oxide loading in a virtually insoluble matrix, which allows the copper ions to be extracted only down to a depth of about 50µ (0·002 in.)[22]. Consequently, there is no advantage in applying the paint layer thicker than this. In contrast, paints of the soluble matrix type usually have a lower toxic loading, but the leaching rate can be more readily controlled by adjusting this loading and the dissolution rate of the matrix. The outstanding advantage of the soluble matrix paints is that their effective lives can be extended by increasing the thickness of the layers applied. Paints of both types, and more recently developed ones, have resisted fouling for 1–2 years in Sydney Harbour during acceptance testing to Australian Standards

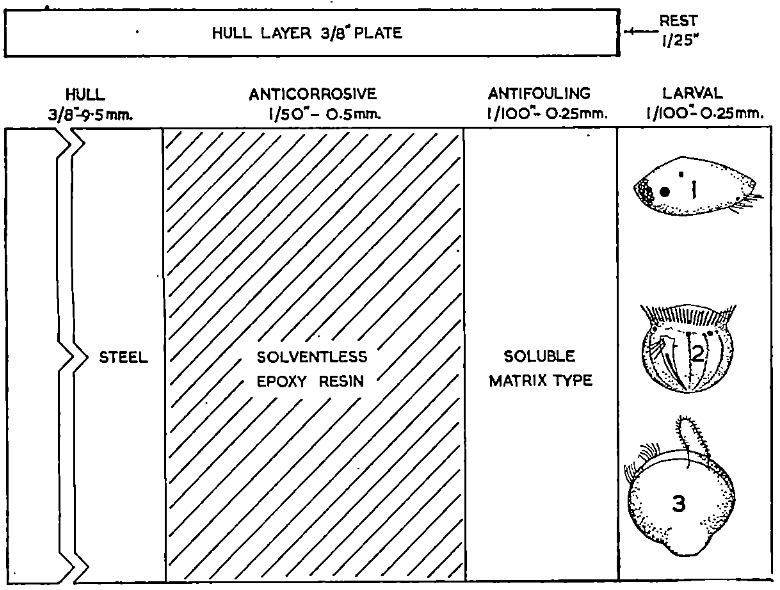

Fig. 1. Above, scale drawing showing the relative widths of the hull and the rest (anticorrosive, antifouling and larval layers); below, diagrammatic enlargement of the latter layers. 1, 2 and 3 represent an approaching barnacle, bryozoan and bivalve mollusc larva respectively

Specification K129. These tests include raft evidence of 12-months' fouling- and corrosion-free performance, followed, after retouching and re-immersion of the test plates, by similar performance for a further 6 months. One of these paints afterwards resisted fouling satisfactorily for two years when applied to a ship moored in reserve[23]. These encouraging results were obtained with thin layers of antifouling paint (0·0015–0·0030 in.); it would be of considerable interest to ascertain how long thick coats (0·005–0·01 in.) of the cuprous oxide, soluble matrix types now available would remain effective.

The function of the anticorrosive layer is to prevent sea-water penetrating through to the hull and causing corrosion. The use of cuprous oxide for antifouling raises an additional problem, since copper compounds can enter into galvanic reactions with the iron of the hull. This is the main disadvantage with cuprous oxide antifouling paints and one of the reasons for seeking alternatives among the toxic organic compounds. Redfield[24] suggested that the logical method of overcoming this kind of problem was to use an anticorrosive layer with impermeable and electrically insulating properties. Such a layer should prevent copper ions from the antifouling layer reaching the hull and should also insulate the hull from sea-water and thus prevent the completion of local circuits through that medium. Wisely[25] tested a solventless epoxy resin as an anticorrosive layer, since those resins were reputed to have the qualities stipulated by Redfield, together with the very desirable feature of strong adhesion to properly prepared metal surfaces. The results of these experiments were promising. The steel beneath the epoxy resin was still bright after 44 months' continuous immersion in the sea. Moreover, the antifouling paint applied over the resin resisted fouling for nearly 32 months, which was longer than could have been expected from previous experience in the use of this paint.

These results suggest that an effective hull protection system can be established by appropriately preparing the hull surface and then applying a solventless epoxy resin to it, followed by a thick layer of cuprous oxide, soluble matrix type, antifouling paint (Fig. 1). The thickness of the antifouling layer shown in this figure is that estimated for a relatively soft and erosion-prone type of paint; this might be expected to last several years. However, if one of the harder plasticized paints was used the layer could be much thinner. Experience in the use of epoxy resin is as yet too limited to indicate the optimum thickness. One of the critical points concerns the ability of the epoxy resin to maintain its characteristic properties and integrity during prolonged immersion on hulls. Ship patch trials would seem to be the most satisfactory method for evaluating these and related issues.

A test area of 250 sq. ft. aimed at assessing the potential of the foregoing system was applied to an Australian ship in September 1963, using conventional dockyard methods and labour. The area was wet sandblasted, using a soluble rust inhibitor additive (trisodium phosphate/potassium bichromate mixture), followed by washing down with fresh water containing a trace of additive. The area was then allowed to dry thoroughly. The epoxy resin applied was 'Araldite Resin 714' (now known as 'Resin MY752') supplied by Ciba Co. Pty., Ltd., Sydney. This was used in the proportions: resin 714, 3·7 kg; hardener 'HY830', 2·3 kg; accelerator 'DY830', 66 g; thixotropic agent (SiO_2), 113 g. Three brushed coats gave an estimated thickness of 0·025–0·035 in., which was thicker than desired. Four coats of 'International Anti Fouling Red 92027', supplied by International Majora Paints Pty., Ltd., Sydney, were then rolled on, giving an estimated thickness of 0·004–0·008 in. This particular paint was used because after 33 months' raft immersion testing there was no evidence of a surface residual matrix layer building up; this suggested it was not a continuous contact type in the strictest sense, and might have had affinities with the plasticized soluble matrix types. It should be noted that the thickness applied was much greater than that recommended normally by the manufacturers. The performance of the complete system, though not identical with that shown in Fig. 1, should permit an estimate of the latter's potential. Application details will be presented later with docking reports.

This work is part of a programme on the biology of fouling organisms carried out in co-operation with the Royal Australian Navy.

ACTINOMYCIN *D* AND MESSENGER-RNA TURNOVER

By Dr. ANTHONY C. TRAKATELLIS, Prof. A. E. AXELROD
and Dr. M. MONTJAR

Biochemistry Department, School of Medicine, University of Pittsburgh

RATES of metabolic turnover of messenger ribonucleic acids (*m*RNA) from various sources have been investigated intensively in recent years. Levinthal *et al.*[1] observed that *m*RMA of *B. subtilis* possessed a rapid turnover with an average half-life of 2·5 min. In sharp contrast, others have reported that *m*RNA of reticulocytes appears to be stable[2,3]. These extreme cases emphasize the necessity of investigations on *m*RNA turnover with particular reference to the regulatory mechanisms of *m*RNA synthesis and decay in different systems.

Original investigations with rat liver gave rise to the speculation that the template for protein synthesis in this tissue may be stable[4]. However, these results were contradicted by subsequent findings that inhibition of RNA synthesis with actinomycin caused a breakdown of polysomes which, according to the authors, resulted from the rapid *m*RNA turnover[5,6]. In recent experiments, Revel and Hiatt[7], utilizing actinomycin *D*, have again suggested that a stable template exists in rat liver. The stability of rat liver *m*RNA is obviously a subject of present-day controversy. In pulse-labelling experiments to be published elsewhere, we have found that, under steady-state conditions, the average half-life of mouse liver polysomal *m*RNA is approximately 2 h. It therefore becomes important to investigate the decay of *m*RNA of mouse-liver polysomes after inhibition of RNA synthesis by actinomycin *D*. In this situation the metabolism of *m*RNA may differ from that existing in a normal steady state and a comparison of turnover rates of *m*RNA under these two conditions may provide information regarding the regulatory mechanism of *m*RNA metabolism. Indeed, using actinomycin *D*, we have found the average half-life of mouse liver *m*RNA to be 8–12 h.

Male adult mice of the *C57Bl/6J* strain purchased from the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, were used in our experiments. Actinomycin *D* was a generous gift from Dr. Elmer Alpert of Merck Sharp and Dohme, West Point, Pennsylvania. Orotic-6-^{14}C acid hydrate (specific activity = 3·45 mc./m.mole) and DL-leucine-1-^{14}C (specific activity = 22·3 mc./m.mole) were obtained from the New England Nuclear Corporation, Boston, Mass. Preparation of purified ribosomes (*p*-ribosomes) by centrifugation through 2 layers of sucrose, and their fractionation by zone centrifugation analysis in a linear sucrose gradient have been described previously[8]. RNA was liberated from *p*-ribosomes by treatment with sodium dodecyl sulphate[9] and fractionated on a linear sucrose gradient. Radioactivities of the various RNA fractions were determined by the procedure of Staehelin *et al.*[10] with minor modifications as follows. 1 ml. of 0·6 N perchloric acid was added to each sample after addition of 20 mg of 'Celite' (diatomaceous silica of John S. Manville Co.) and 0·5 ml. of a bovine serum albumin solution (4 mg per ml.) serving as a co-precipitant. Resulting precipitates were collected by suction on filter-paper disks (Whatman No. 540) layered with 20 mg of 'Celite' in a stainless-steel filtration apparatus (*E*–8*B* apparatus, Tracerlab) and washed successively with 6 ml. of 0·5 N perchloric acid, twice with 5 ml. of isopropanol–ethyl ether (1 : 2) and, finally, with 5 ml. of isopropanol–ethyl ether–chloroform (2 : 2 : 1). Dried precipitates were transferred to glass-counting vials and 1 ml. hydroxide of hyamine (methanol solution of *p*-(diisobutylcresoxyethoxy ethyl) dimethyl benzyl ammonium hydroxide, Packard Instrument Co.) solution added. After 1 h at room temperature, 9 ml. of a 0·5 per cent solution of 2,5-diphenyloxazole in toluene were added and radioactivity measured in a Packard 'Tri-Carb' scintillation counter.

A typical experiment demonstrating effects of varying doses of actinomycin *D* on pulse-labelled liver RNA is shown in Fig. 1. The sedimentation pattern observed in the control animal (Fig. 1, I) has been analysed extensively in recent investigations on the sedimentation behaviour of pulse-labelled liver RNA[10–12]. This diagram clearly shows 3 peaks, *a*, *b* and *c*, and an area between *b* and *c* with high radioactivity. The radioactive peaks *a* and *b* coincide with the 29*S* and the 18*S* ribosomal RNA (*r*RNA), respectively. Peak *c*, which corresponds to an

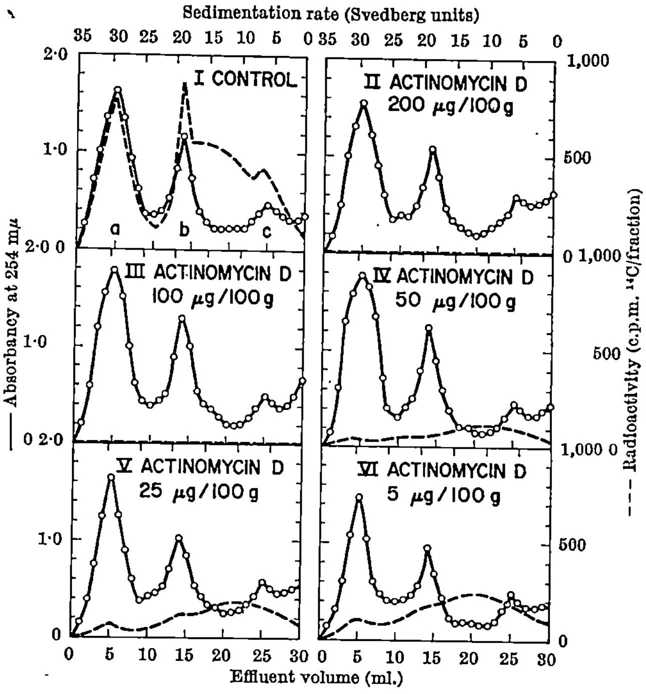

Fig. 1. Sedimentation patterns of pulse-labelled liver RNA from normal (I) and actinomycin *D*-treated (II–VI) mice. Mice weighing 25 g were injected intraperitoneally with the indicated amounts of actinomycin *D*. After 4 h, each mouse received 15 µc. of orotic-6-^{14}C acid hydrate by intraperitoneal injection and was killed 4 h later by decapitation after ether anæsthesia. Liver *p*-ribosomes were prepared and RNA liberated by stirring the ribosomal pellet for 3 min at 37° C in 1 ml. of 0·5 per cent sodium dodecyl sulphate. The mixture was layered over 30 ml. of a cold linear sucrose gradient (0·5–1·0 M) containing 0·005 M *tris*-HCl, *p*H 7·2. After centrifugation for 40 h at 25,000 r.p.m. and 1° C in the *SW* 25 Spinco rotor, 1 ml. fractions were collected from a needle inserted through the bottom of the centrifuge tube and their absorbancies at 254 mµ and radioactivities determined. Sedimentation constants of RNA fractions were determined by calibrating the sucrose linear gradient with the 18*S* and 29*S* ribosomal RNA (ref. 10)

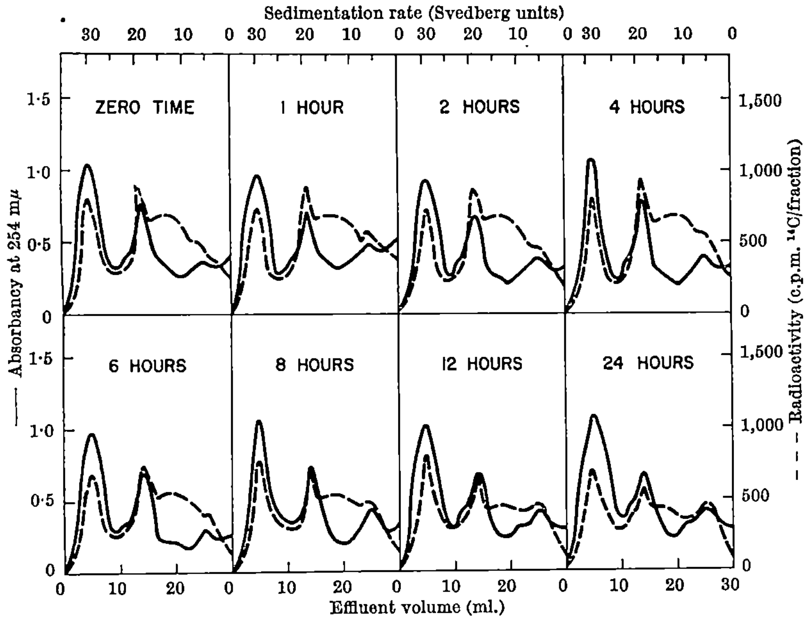

Fig. 2. Sedimentation patterns of pulse-labelled liver RNA at varying times after administration of actinomycin *D*. Mice weighing 25 g were injected intraperitoneally with 15 μc. of orotic-6-^{14}C acid hydrate. Four hours later, each mouse received intraperitoneally 100 μg of actinomycin *D*/100 g body-wt. A mouse killed immediately after injection of actinomycin *D* served as the zero time control. Other animals were killed as indicated at the varying time-intervals after injection of actinomycin *D* and sedimentation patterns of pulse-labelled RNA determined as in Fig. 1

RNA component with an approximate sedimentation constant of 4·5–5*S*, consists of labelled transfer RNA (*s*RNA). The radioactive area *b–c* possesses a high specific activity and is heterogeneous with components possessing sedimentation rates ranging from approximately 4·5*S* to 20*S*. Accumulated evidence supports the view that this area consists of a spectrum of *m*RNA molecules[10–12]. Intraperitoneal injection of 200 μg/100 g body-wt. actinomycin *D* 4 h prior to administration of orotic-6-^{14}C acid hydrate blocked completely the synthesis of *m*RNA and *r*RNA (Fig. 1, II). In a separate experiment, we noted that 9 of 10 mice receiving this dose of actinomycin *D* died within 30 h. Philips *et al.*[13] have reported that the LD_{50} of actinomycin *D* for the mouse is approximately 76 μg/100 g body-wt. RNA synthesis was also blocked completely by administering actinomycin *D* at a dose-level of 100 μg/100 g body-wt. (Fig. 1, III). Doses of 50, 25 and 5 μg of actinomycin *D*/100 g body wt. produced approximately 85 per cent (Fig. 1, IV), 70–75 per cent (Fig. 1, V) and 60 per cent (Fig. 1, VI) inhibition of RNA synthesis, respectively. Percentage inhibition was computed from the total c.p.m. recovered, the control values being taken as 100 per cent, Similar results were obtained when actinomycin *D* was injected only 30 min prior to injection of orotic-6-^{14}C acid hydrate.

The decay time of radioactively labelled *m*RNA was determined in the experiment recorded in Fig. 2. Mice received an intraperitoneal injection of labelled orotic acid followed after 4 h by an intraperitoneal injection of actinomycin *D*. Animals were killed at varying times thereafter and radioactivity of RNA components determined. Since synthesis of RNA is inhibited completely by the dose of actinomycin *D* used, one can with this procedure determine the rate of decay of existing RNA molecules which had been labelled by injection of orotic acid. Decay of *m*RNA became apparent 6 h after injection of actinomycin *D* and continued until the experiment was terminated at 24 h (Fig. 2). Total c.p.m. of *m*RNA were calculated at various times after administration of actinomycin *D* and expressed as percentage of the zero time or control value (broken line curve in Fig. 3).

Capacities of liver ribosomes to incorporate DL-leucine-1-^{14}C at varying times after injection of actinomycin *D* were determined and results plotted in Fig. 3 (unbroken line). The inhibitory effects of actinomycin *D* on DL-leucine-1-^{14}C incorporation paralleled the rate of decay of labelled *m*RNA subsequent to administration of the same dose of actinomycin *D* (Fig. 3). It should be noted that the addition of actinomycin *D* (1–2 μg/ml.) *in vitro* to the amino-acid-incorporating system had no effect on ability of ribosomes to incorporate DL-leucine-1-^{14}C. In other experiments utilizing zone centrifugation analysis of purified ribosomes, we observed that 40–60 per cent of liver polysomes were de-aggregated to 73*S* ribosomes 8 h after injection of 100 μg of actinomycin *D*/100 g of body-wt. These results have been noted previously[5] and are in agreement with the pulse-labelled and incorporation investigations described here.

An average half-life for mouse liver *m*RNA of about 8–12 h was obtained from our investigations reported here (Fig. 3). This value is considerably greater than that of 2 h which we observed under steady-state conditions[12]. This apparent decrease in decay of polysomal *m*RNA after inhibition of RNA synthesis by actinomycin may be attributed to several factors. We have observed in an experiment similar to that described in Fig. 2 that

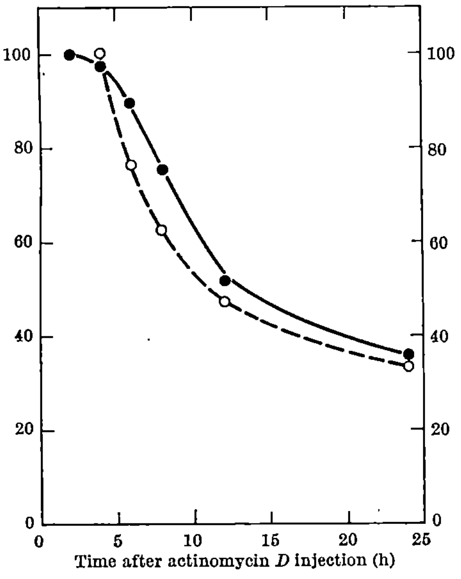

Fig. 3. Effect of injection of 100 μg of actinomycin *D* per 100 g of body-weight on decay of labelled liver *m*RNA and capacity of liver ribosomes to incorporate DL-leucine-1-^{14}C. Broken line represents the decay curve of labelled *m*RNA and was plotted from data presented in Fig. 2. Incorporation investigations were conducted as follows. Mice were injected intraperitoneally with actinomycin *D* and killed at the indicated times. The complete cell-free amino-acid incorporating system contained purified ribosomes (derived from 0·6 g of liver and containing 500 μg of RNA) suspended in 0·4 ml. Hoaglands's salt buffer (ref. 8), 3·2 μmoles $MgCl_2$, 30 μmoles *tris*-HCl (*p*H 7·6), 2·0 μmoles β-mercaptoethanol, 10 μmoles phosphoenolpyruvic acid, 10 μg pyruvate kinase, 1 μmole ATP, 0·4 μmoles GTP, 0·1 μmoles DL-leucine-1-^{14}C and 0·1 ml. of dialysed post-microsomal supernatant derived from a 25 per cent liver homogenate in Hoaglands's medium A (0·005 M *tris*, 0·025 M KCl, 0·005 M $MgCl_2$ and 0·25 M sucrose) after removal of the microsomal fraction (ref. 14) and dialysis at 2° C for 25 h against a 50-fold volume of Hoaglands's salt buffer containing 0·005 M β-mercaptoethanol. Final volume was brought to 1 ml. with Hoaglands's salt buffer. After incubation at 37° C for 30 min, incorporation was stopped by addition of 1 ml. of 1 M NaOH. The mixture was kept at room temperature for 1 h and the protein then precipitated with $HClO_4$, filtered, washed, solubilized with hyamine and radioactivity measured in a Packard 'Tri-Carb' scintillation counter (ref. 5). Controls utilized in each experiment were kept at 0° C and 1 M NaOH added at the beginning of incubation. A mouse killed immediately after injection of actinomycin *D* served as the zero time control. Degree of incorporation of DL-leucine-1-^{14}C (c.p.m. per mg RNA) is expressed as percentage of the zero time control value (3,012 c.p.m. per mg RNA) in the unbroken line

Left: ●, incorporation ability expressed as percentage of the control; right, ○, total c.p.m. of *m*RNA expressed as percentage of the control a labelled nuclear RNA fraction with sedimentation pattern similar to that of polysomal *m*RNA can be found in nuclei as long as 4 h after injection of actinomycin *D*. Gradual release of this labelled nuclear RNA fraction, presumably *m*RNA, into the cytoplasm would obscure the experimental determination of the true decay time of ribosomal *m*RNA. An apparent increase in decay time of labelled *m*RNA would be observed and the true metabolic turnover of polysomal *m*RNA could be determined only after the labelled nuclear *m*RNA fraction had been exhausted. However, we cannot dismiss the possibility that *m*RNA synthesis may be related to *m*RNA breakdown via regulatory mechanism of as yet unknown nature. Inhibition of *m*RNA synthesis by actinomycin *D* would then be expected to influence the rate of *m*RNA breakdown, perhaps, as noted in this article, in the direction of inhibition.

HEAT OF RESPIRATION AS A POSSIBLE CAUSE OF ERROR IN THE ESTIMATION BY PSYCHROMETRIC METHODS OF WATER POTENTIAL IN PLANT TISSUE

By Dr. H. D. BARRS

C.S.I.R.O. Irrigation Research Laboratory, Griffith, New South Wales, Australia

TWO types of miniature wet and dry junction thermocouple psychrometer have been used for the determination of water potentials in plant tissues[1–5]. Spanner[5] devised a psychrometer in which one junction is wetted by the Peltier cooling effect. The quantity of water involved is very small, and the wet junction so formed lasts only for a short time, being renewed before each reading. Between humidity readings, when the 'wet' junction is dry, the instrument may be used to compare the dry bulb temperature within the chamber with that of the bath. In the second type of psychrometer[6] the wet junction is permanent, being formed by dipping a silver cylinder, which is soldered to the free junction, into water before inserting the couple into the chamber. It is not possible to observe dry-bulb temperatures within the chamber owing to the permanent nature of the wet junction.

This article is a preliminary report of a comparison of results from the two types of psychrometer when used to determine water potentials of leaves of plants.

The couple design referred to here as due to Spanner differs slightly from the original in that chromel-*p* and constantan wires have been substituted for bismuth and bismuth–tin[7]. In other respects the techniques used were essentially as described by Spanner[5], and Richards and Ogata[6], the outputs from both types of couple being measured with a reflecting galvanometer. The chambers were immersed in a controlled temperature water bath and the design of the couples ensured the reference junctions were held at bath temperature soon after immersion.

Early experiments using *Pelargonium zonale* indicated that the Spanner couple was consistently measuring larger water potentials than the Richards couple. A closer examination of the results showed that, between humidity readings, and while the 'wet' junction of the Spanner couple was dry, there was still an appreciable output. This was in the reverse direction to the output when recording humidities with the wet junction present, indicating that the 'wet' junction was warmer than the reference junction. During calibration when the chamber contained filter paper wetted with sodium chloride solution, there was no output from the dry couple, suggesting that the chamber was warmer only when it contained plant material. Further information on this point was obtained using dry Richards couples (that is, silver ring without water). Fig. 1 shows that these also measured temperature rises within the chamber when living tissue was present. The temperature rise with two layers of *Pelargonium* leaf (curve *a*) is clearly greater and maintained for a shorter time than the rise using a single layer (curve *b*). Conversion of these temperature differences to water potentials gives values of approximately 7 and 1·8 bars respectively, though the signs of the thermocouple outputs are, of course, the reverse of those normally obtained when a wet junction is present. It seemed likely that this rise was due to the liberation of heat accompanying the respiration of the tissue, and that the decline to bath temperature occurred when the oxygen-level within the chamber had fallen to some critical level and respiration at normal rates could no longer be maintained.

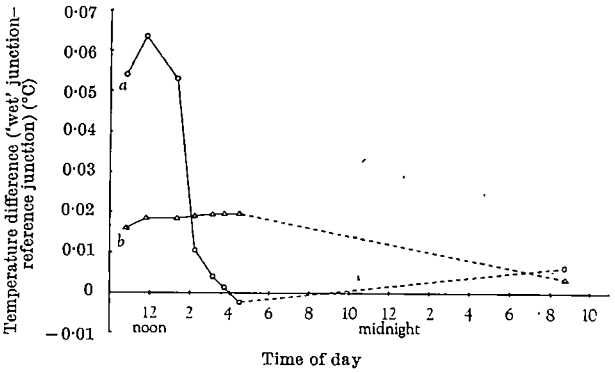

Fig. 1. Effect of two layers (curve *a*), and one layer (curve *b*), of *Pelargonium* leaf tissue on temperature within equilibration chambers, referred to bath temperature. Set up 10 a.m. with dry Richards couple

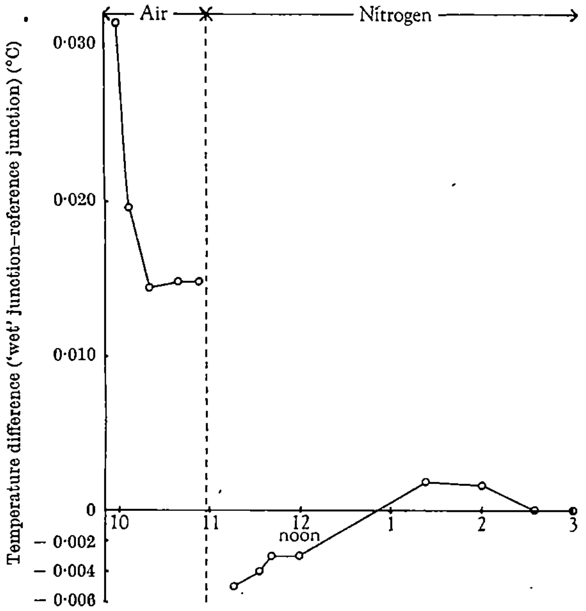

Fig. 2. Effect of replacing air by nitrogen on temperature within chamber referred to bath temperature. Set up 9.50 a.m. with dry Richards couple and one layer of *Pelargonium* leaf

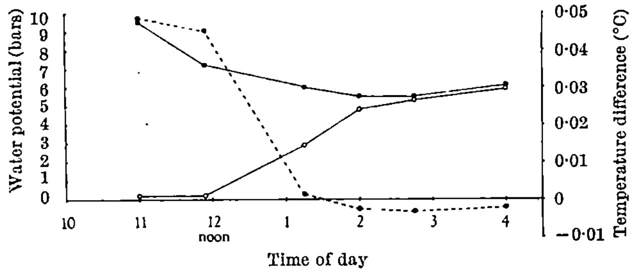

Fig. 3. Water potential (●——●) and chamber temperature referred to bath temperature (●- - -●) using a Spanner couple and water potential (○——○) using a Richards couple

Fig. 2 shows how the rise in temperature within the chamber could, in fact, be abolished by substituting nitrogen for air ; the leaf apparently becoming slightly colder than the reference junction for some time before thermal equilibrium was finally reached. This latter behaviour has frequently been noted although not always. The effect of nitrogen in abolishing the temperature rise suggests that the rise is largely dependent on continued aerobic respiration. Fig. 3 compares water potentials estimated by a Richards and a Spanner couple. The couples were in separate chambers and each chamber contained a double layer of the same *Pelargonium* leaf. Fig. 2 also shows the temperature of one chamber as measured by the Spanner couple when dry. These latter measurements indicate a very considerable reduction in respiration between twelve noon and 1.30 p.m. ; it can be seen that at the same time the reading of the Richards couple began to rise markedly and by 2.45 p.m. approximated closely to the reading of the Spanner couple. Fig. 2 also shows water potential as rising finally. There is evidence, to be described in detail elsewhere, that this is associated with the death of the tissue and liberation of the cell contents. The difference between the observed water potentials before 2.45 p.m. is suggested as being largely due to the fact that the Richards couple only permits measurement of wet-bulb depression against bath temperature (the temperature of the reference junction), whereas the Spanner couple permits a measure of actual chamber dry-bulb temperature immediately before the cooling current is passed and the wet-bulb depression noted. Reference to Fig. 1 curve *b* shows that for one layer of *Pelargonium* leaf the rise in temperature within the chamber could be maintained for more than 4 h and in fact one layer has usually been able to maintain such an elevation for 8 h or longer. Ehlig[4], working with the Richards couple, reports that equilibrium and a steady output are obtained in 2·5–6 h for cotton, pepper and trefoil. This has been found to apply to *Pelargonium*. Hence it is quite possible for a Richards couple to reach equilibrium in a chamber the dry-bulb temperature of which is higher than bath temperature. This may lead to an underestimate of the water potential of the tissue, here presumably by about 1·8 bars.

The Spanner couple, on the other hand, would appear, to a first approximation at least, not to be affected by moderate rises in chamber temperature. This is provided that the reference point for its output as a psychrometer is taken as its output when the 'wet' junction is dry, rather than the mechanical zero of the indicating galvanometer. An example may clarify this; suppose bath temperature to be 25·00° C, chamber temperature to be 25·01° C and wet-bulb temperature to be 24·98° C, then the correct depression will be 25·01–24·98 = 0·03° C, and the Spanner couple will approximate to this provided it has been used to estimate chamber temperature as well as wet-bulb depression. The chamber temperature cannot be measured by the Richards couple, owing to the permanent nature of the wet junction, hence the observed depression will be 25·00–24·98 = 0·02° C, resulting in a 33 per cent error. On this basis it should be possible, given a sufficient quantity of turgid tissue, to so heat the chamber that the wet junction of the Richards couple becomes warmer than the dry junction, reversing the output of the couple compared with the normal direction found during calibration. As Table 1 shows, this has indeed been observed using two layers of *Pelargonium* leaf. The final change in sign of output and rise to a high level would be explicable in terms of a marked decline in respiration.

Table 1

Time	10.45	11.12	12.00	1.18
μV	−0·46	−0·52	−0·33	+3·87

(Set up 9.45 a.m. with dry Richards couple)

Table 2

Plant	Cotton	Pepper	*Pelargonium*
Respiration	10·6, 11·8	10·4, 11·6	31·5, 32·8

(Respiration as μLO_2/15 min/9 cm^2 leaf)

The results presented here are perhaps extreme. Table 2 shows that the respiration rate of the *Pelargonium* was three times as high as that of cotton and pepper. It may be that errors due to temperature rise in the equilibration chamber are less important for many species. This is being investigated together with the possibility of preventing temperature rise by providing a suitable heat sink for the leaf. A more critical evaluation of the performance of the Spanner couple, and in particular the assumption that when dry it approximates leaf temperature, is in progress. A full account of this work will be published shortly.

I thank Dr. R. O. Slatyer, C.S.I.R.O. Division of Land Research and Regional Survey, Canberra, for suggesting the problem and for his advice, and Mr. E. R. Hoare, officer-in-charge, C.S.I.R.O. Irrigation Research Laboratory, Griffith, New South Wales, for advice and provision of facilities.

TRIGONAL OR TETRAGONAL DISTORTIONS AND THE MAGNETIC PROPERTIES OF TRANSITION METAL IONS WITH TRIPLY ORBITALLY DEGENERATE GROUND TERMS

By DR. B. N. FIGGIS
Department of Chemistry, University of Western Australia

PROF. J. LEWIS and DR. F. MABBS

AND

DR. G. A. WEBB
Department of Chemistry, University College, London

THE magnetic properties of transition metal complexes have long been of interest in determining stereochemistry and valency in transition metal ions[1]. Recently, measurements have been used to differentiate between octahedral and tetrahedral stereochemistry in complexes, distinction being based on the absolute value of the magnetic measurements on complexes with these stereochemistries[2]. The temperature variation of the magnetic properties of octahedral and tetrahedral complexes of the transition elements has been interpreted in terms of the splitting of the metal d orbitals by the combined effects of the ligand field and spin-orbit coupling[1,3,4]. In most previous treatments the ligand field has been assumed to be of cubic symmetry. However, the importance of the deviation of the ligand field from cubic symmetry has been recognized in certain cases. Most frequently the low symmetry has been dealt with for systems with A or E ground terms[5-7] because these terms respond to departures from cubic symmetry in a fairly simple manner. Systems with T ground terms, however, present a much more difficult problem, and with the exception of the ${}^2T_{2g}$ term[8,9] they have been the subject of detailed consideration in only few instances[5,8-10].

We have reported[9,11] calculations for the effect of a trigonal or tetragonal distortion on the configurations t_{2g}^1, t_{2g}^5 and $e^4 \cdot t_2^5$, which give rise to a ${}^2T_{2(g)}$ ground term*. These calculations have now been extended to cover configurations which give rise to ${}^3T_{1(g)}$, ${}^4T_{1(g)}$ and ${}^5T_{2(g)}$ ground terms, this covering all the T ground terms possible for the transition elements.

Our results refer only to the average magnetic moments as determined on powdered samples, and as pointed out previously[8] they do not give as accurate values of the parameters which determine the distribution of the energy levels in a T ground state, as do more sophisticated techniques such as electron spin resonance or magnetic anisotropy. However, they do enable a great deal of information to be obtained from the more readily available powder data.

In considering magnetic properties of complexes two different classes of T ground terms must be recognized. They are, on one hand, the $T_{2(g)}$ terms arising from the configuration t_{2g}^1, $e^2 \cdot t_2^2$, t_{2g}^5, $t_{2g}^4 \cdot e_g^2$ and $e^4 \cdot t_2^5$, and on the other hand, the $T_{1(g)}$ terms from the configurations t_{2g}^2, $e^2 \cdot t_2^1$, t_{2g}^4, $t_{2g}^5 \cdot e_g^2$ and $e^4 \cdot t_2^4$. It is convenient to discuss the two classes separately.

T_2 terms. The effect of asymmetric ligand fields on the ${}^2T_{2g}$ ground terms has been considered previously[8,9,11]. A similar treatment using a tetragonal or trigonal distortion has been carried out here for the ${}^5T_{2(g)}$ terms. The asymmetric ligand field component (l.h.s.) and spin-orbit coupling (r.h.s.) split the ${}^5T_{2(g)}$ term as shown in Fig. 1. For an intermediate perturbation by both spin-orbit coupling and asymmetric ligand field components the splitting is given in the centre of the figure. It is this last condition which is the major concern of this discussion.

We define Δ as the splitting of the orbital degeneracy of the ${}^5T_{2(g)}$ term by the asymmetric ligand field component, spin-orbit coupling being neglected, and it is taken to be positive when the orbital singlet is lowest. Fig. 2 shows the behaviour of the magnetic moment for the ${}^5T_{(2)g}$ term as a function of the parameter kT/λ. Curves are given for various values of ν, the ratio of the distortion to the spin-orbit coupling constant: that is, $\nu = \Delta/\lambda$. (Here we use λ to denote the value of the spin-orbit coupling constant *in the complex* and λ_0 for the free-ion value.)

Previous work has indicated that it is also necessary to consider a reduction in the orbital part of the magnetic moment operator. This reduction has been associated with electron delocalization on to the ligand atoms[8,9,12]. It is normally allowed for by introducing a constant, k, into the matrix elements of the orbital angular momentum operator. The magnetic moment and spin-orbit coupling operators for the Z direction then become: $(kL_z + 2S_z)$ and $kL_z S_z$ respectively.

We have allowed k to vary from 1 to 0·5. The calculated curves for two values of k and negative values of the spin-orbit coupling constant are shown in Fig. 2. We have only provided results for negative values of λ because these apply to the configuration $t_{2g}^4 \cdot e_g^2$, as our experimental results for the ${}^5T_{2(g)}$ case are confined to compounds of octahedral bivalent iron.

As expected, and as observed in the corresponding calculations for the ${}^2T_{2(g)}$ ground terms, a decrease in the value of k reduces the magnetic moment, bringing it closer to the 'spin-only' value of 4·90 Bohr magnetons. For negative values of Δ (ν positive) the overall variation of the moment with temperature is reduced as the magnitude of the distortion is increased. On the other hand, for positive values of Δ, a very significant change in the

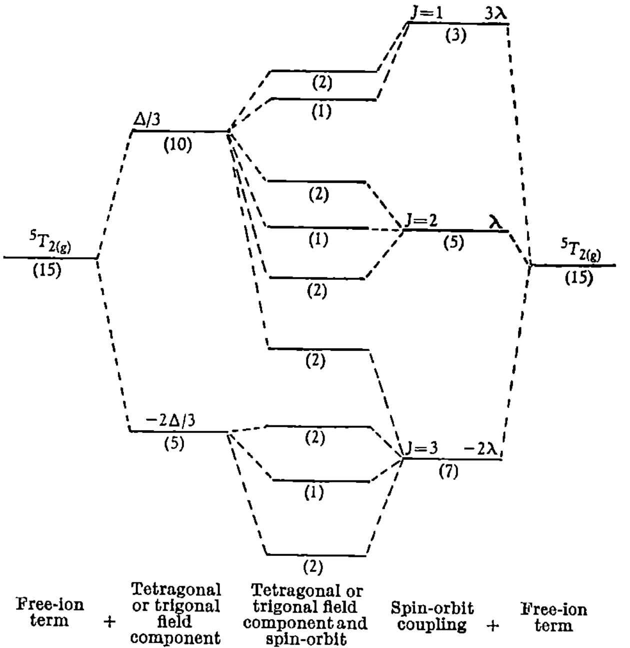

Fig. 1. Splitting pattern for the ${}^5T_{2(g)}$ term under the action of a tetragonal of trigonal ligand field component and spin orbit column

---

* The brackets are included in the term symbols, for example, ${}^2T_{2(g)}$, to indicate that the results apply to both octahedral and tetrahedral stereochemistries.

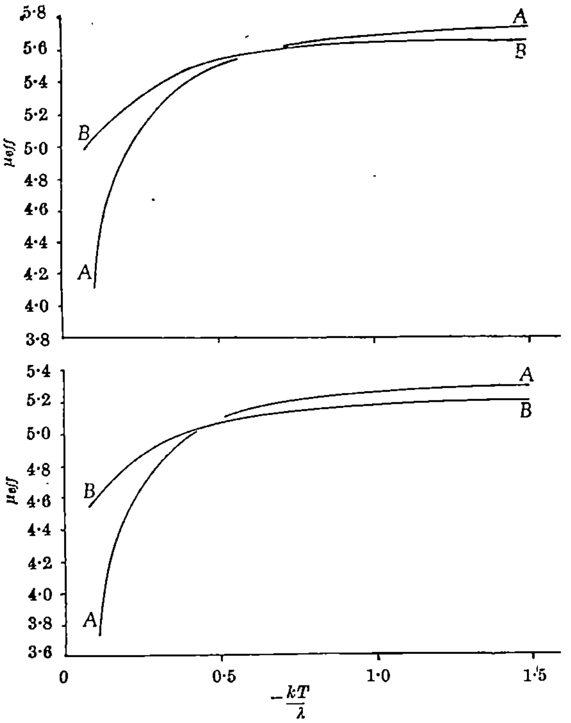

Fig. 2. Above, k, 1·0; below, k, 0·5. A, ν, −3·0; B, ν, +3·0

variation of the magnetic properties with temperature occurs, the dependence of the moment on temperature being much more marked.

In general, ligand field components of low symmetry have comparatively little effect on the magnetic properties of the ${}^5T_{2(g)}$ ground term unless they raise its orbital degeneracy by an amount greater than the spin-orbit coupling constant. It is, therefore, important to consider the effects of asymmetric ligand fields for the compounds of 1st row transition elements rather than for 2nd and 3rd row elements. For values of ν greater than about 10 our treatment is not satisfactory, as the asymmetric component of the ligand field potential is then of the same order as the primary cubic ligand field. Under such conditions the perturbation methods which we have used are no longer applicable.

$T_{1(g)}$ *terms.* Any configuration of a transition element ion that gives rise to an F ground term, in addition, leads to a P term of the same spin multiplicity. This P term is separated from the ground F term by an energy which depends on the inter-electronic repulsion parameters of the system. Under the influence of a cubic ligand field, both these terms give rise to $T_{1(g)}$ terms which interact. The degree of interaction depends on the relative magnitudes of the interelectronic repulsion and the ligand field parameters. It is convenient to express the composition of the ground $T_{1(g)}$ term as a linear combination of the $T_{1(g)}$ terms in the free-ion limit:

$$U_{T1} = (1 + c^2)^{-\frac{1}{2}}[U_{T1(F)} + cU_{T1(P)}]$$

where:

$$c = \frac{6Dq + E}{4Dq}$$

E is the lower root of the equation:

$$E^2 + (6Dq - Z)E - 6Z - 16D^2q^2 = 0$$

Z is the ratio of the $F - P$ term separation in the complex to the cubic ligand field parameter, namely:

$$Z = [E_{(P)} - E_{(F)}]/Dq$$

The admixture coefficient c, which may often be determined with the aid of the optical spectrum of the complex, lies between 0 and −0·5. For the weak field limit ($Z \rightarrow \infty$), $c = 0$, while for a medium or strong field ($Z \rightarrow 0$), $c = -0{\cdot}5$. For more general application it is convenient to employ a constant A, which is a measure of the strength of the ligand field relative to the interelectronic repulsion energy, given by $A = (1{\cdot}5 - c^2)/(1 + c^2)$. The classification of ligand field strengths has been discussed elsewhere[3].

The variation of the magnetic moments of the ${}^3T_{1(g)}$ and ${}^4T_{1(g)}$ terms is given in Fig. 3 as a function of the parameters k, ν and kT/λ. These results are applicable to systems for which λ is negative, for example, $e^4{\cdot}t_2^4$ (tetrahedral Ni^{2+}) and $t_{2g}^5.e_g^2$ (octahedral Co^{2+}). It is obvious from these curves that changes in the parameters make a significant difference to the variation of the magnetic properties of the ions with temperature. As with the ${}^5T_{2(g)}$ term, the variation is much more marked for positive values of Δ.

In considering the data it is important to take into account the relationship between the orbital splitting parameter, Δ, and the magnitude of the low symmetry ligand field component which is responsible for it. A ligand field potential of cubic symmetry with a tetragonal or trigonal component superimposed may be put in the form:

$$V = D(x^4 + y^4 + z^4 - 3r^4/5) + C(z^2 - r^2/3)$$

Conventionally, the matrix elements arising from the first, cubic, term in this potential are expressed as multiples of a number, q, and the splittings of the free-ion terms are then integral multiples of the parameter Dq. Similarly, if we define a parameter Cp for the second, low symmetry, term in the potential, then the splittings of T terms by an asymmetric ligand field component are simple multiples of Cp. In the parameter Cp, p is equivalent to q of cubic symmetry. In order to express Δ as a function of Cp we must consider tetragonal and trigonal symmetry separately. The splitting of the T terms in units of Cp are given in Table 1, as a function of both the magnitude of the cubic ligand field and symmetry. For a given low symmetry ligand field component the splitting of the various terms may be greatly different. In the case of $T_{1(g)}$ ground terms, μ_{eff} is very dependent on the degree of mixing with the higher $T_{1g}(P)$ term.

By using curve fitting procedures we have applied the above theory to magnetic measurements we have performed on a number of complexes of octahedral divalent

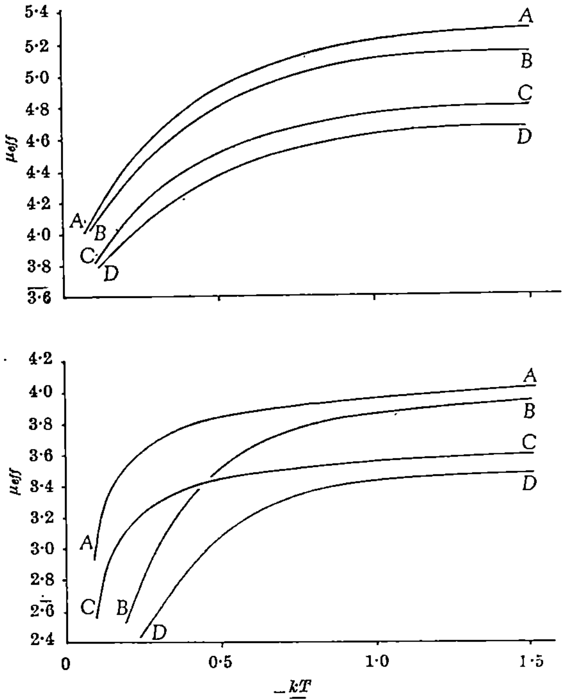

Fig. 3. Above, ${}^4T_{1(g)}$; below, ${}^3T_{1(g)}$

Medium or strong field ($A = 1$)	$-6Cp$	$6Cp$

iron, octahedral bivalent cobalt and tetrahedral bivalent nickel. Figs. 4–6 show the agreement which may be obtained in this way and Table 2 contains results for a representative list of the complexes we have investigated. It is important to appreciate that the value of Δ obtained by this procedure may, in certain instances, be in error by as much as 50 per cent. This uncertainty arises from ambiguity in the curve-fitting process.

In some instances it is possible to compare Δ obtained from our data with its value assessed by other techniques. In the case of Fe(II) comparison may only be made with the low-temperature measurements on the fluorsilicate complex. From data gathered at liquid helium temperatures, Δ has been reported to be 1,200 cm^{-1} (ref. 13). For Co(II) complexes there may be some ambiguity in the interpretation of the experimental results. The data often may be interpreted in terms of either a negative or a positive value for the distortion parameter, although one of the alternatives usually gives a distinctly better fit. The ambiguity arises from the small curvature of the susceptibility–temperature plots.

×, Experimental results

The electron-spin resonance[8,14] and low-temperature magnetic susceptibility investigations[15,16] on the complex $Co(NH_4)_2(SO_4)_26H_2O$ give values of Δ of about −700 to −1,300 and approximately −1,100 cm^{-1} respectively, although it was found that in the latter case[15] Δ had to be varied somewhat with temperature in order to fit the results. These estimates are in general agreement with the value obtained in this work, that is, −775 cm^{-1}. Low-temperature magnetic susceptibility measurements on the complex $[Co(H_2O)_4Cl_2]2H_2O$ have not been interpreted unambiguously, values of Δ/λ of −1·0 or −5·0 being deduced[17], that is, Δ is approximately +200 or +900 cm^{-1}. The value of Δ obtained from the present work, 375 cm^{-1}, is in reasonable agreement with the lower of these estimates. No independent estimation of Δ in the Ni(II) tetrahedral complexes is available.

For tetrahedral Ni^{2+} the ground term is $^3T_1$. Table 2 contains the data for some of the complexes, the tetrahedral stereochemistry of which has been assigned previously on the basis of spectral and room-temperature magnetic susceptibility data[18,19]. It has been suggested that the reduction in the magnetic moment of the complexes on the replacement of halogens by phosphine

ligands arises from distortions from regular tetrahedral symmetry. From Table 2 it appears that the value of Δ is more or less constant, and the reduction in the magnetic moment on the replacement is to be associated with reduction in k and λ. These observations emphasize that it is important when discussing magnetic results to consider the effects of distortion, reduction in the spin-orbit coupling and orbital reduction parameters together.

A SENSITIVE DOUBLE ANTIBODY IMMUNOASSAY FOR HUMAN GROWTH HORMONE IN PLASMA

By Dr. DON S. SCHALCH* and Dr. MARY L. PARKER

Metabolism Division, Department of Medicine, Washington University School of Medicine, St. Louis, Missouri

DESPITE the successful use of electrophoretic and electrochromatographic methods[1-3] of assaying human growth hormone, many workers have had difficulty with these relatively elaborate procedures. This has prompted us to re-investigate the double antibody method. Non-specific interference from substances in plasma have complicated previous use of the double antibody method, and extraction procedures proved to be rather laborious[4,5]. A double antibody immunoassay for human growth hormone, patterned after a similar immunoassay for insulin[6], using guinea pig anti-human growth hormone serum and rabbit anti-guinea pig γ-globulin serum has proved to be successful. While this method is relatively simple and easy to use, it provides a high degree of sensitivity along with good reproducibility of results.

All dilutions were made with 5 per cent bovine serum albumin (BSA Armour, 30 per cent solution) in a barbital buffer, ionic strength 0·1, *p*H 8·6.

Anti-HGH serum was obtained ten days after the last of three weekly subcutaneous injections of 1 mg human growth hormone (Raben) emulsified in complete Freund's adjuvant.

Rabbits were immunized with 1 mg of guinea pig γ-globulin in complete Freund's adjuvant injected into each foot pad. Subsequent monthly injections were given subcutaneously. Animals were bled by cardiac puncture 10–14 days after the third or subsequent monthly boosters.

Human growth hormone was labelled with iodine-131 by the method of Greenwood, Hunter and Glover[7] as modified by Glick *et al.*[8]. Specific activities of 300–350 mc./mg were obtained.

Pooled normal guinea pig serum was diluted 1 : 200 with 5 per cent BSA barbital buffer.

Duplicate standards of human growth hormone are freshly prepared for each assay with the following concentrations: 0, 0·25, 0·5, 1, 2, 4 and 8 mμg/ml. 0·5 ml. of each standard solution is used in duplicate. Disposable glass tubes, 10 mm × 75 mm, have been found to be most satisfactory for the incubation tubes. 50 μl. of each plasma sample is added to 0·45 ml. 5 per cent BSA barbital buffer for an initial dilution of 1 : 10. 10–100 μl. of plasma in an initial total volume of 0·5 ml. can be used as well. 0·1 ml. of diluted guinea pig antihuman growth hormone serum is then added to each tube. The appropriate dilution of antiserum is that which binds approximately 35–55 per cent iodine-131-labelled human growth hormone added when no competing unlabelled human growth hormone is present in the system. After gentle shaking of the tubes, 0·1 ml. (0·1–0·2 mμg) of iodine-131-human growth hormone is added, the tubes are again shaken and incubated at 4° C for 72 h. At this time, 0·1 ml. of appropriately diluted rabbit anti-guinea pig γ-globulin serum, and finally 0·1 ml. of 1 : 200 normal guinea pig serum are added, the tubes shaken and incubated another 18–24 h at 4° C. The appropriate dilution of rabbit anti-guinea pig γ-globulin serum is one which will completely precipitate all guinea pig γ-globulin in the system. The tubes are then counted in a well autogamma spectrometer. They are then centrifuged at 2,500 r.p.m. for 20 min and the supernatants are aspirated and discarded. The precipitates are washed with cold (4° C) distilled water, recentrifuged at 2,500 r.p.m. for 20 min and the supernatants again aspirated and discarded. The tubes, containing the precipitates, are recounted and the percentage iodine-131-labelled human growth hormone precipitated is calculated.

Table 1. MEAN DIFFERENCE IN PERCENTAGE PRECIPITATION OF HUMAN GROWTH HORMONE BETWEEN DUPLICATE STANDARDS

Human growth hormone standard concentration (mμg/ml.)	Mean difference in % human growth hormone-iodine-131-labelled precipitation between duplicates ± *S.D.*
0	0·8 ± 0·2 (9)*
0·25	1·8 ± 1·2 (9)
0·5	1·7 ± 1·2 (9)
1	1·7 ± 1·5 (9)
2	1·0 ± 0·6 (9)
4	0·9 ± 0·8 (9)
8	0·7 ± 0·3 (9)
Average	1·0 ± 0·7

*No. of duplicate values in brackets.

A standard curve is constructed for each assay (Fig. 1) and the concentration of human growth hormone in each plasma sample is then determined from the percentage

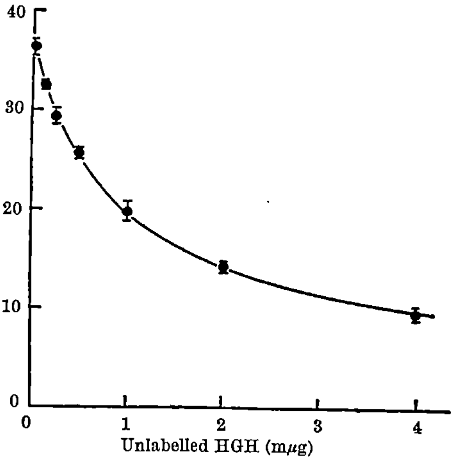

Fig. 1. Human growth hormone-^{131}I (0·1 mμg), guinea pig anti-human growth hormone serum (1 : 120,000), rabbit anti-guinea pig γ-globulin serum (1 : 6), First incubation period, 72 h; second incubation period, 24 h. Each point is the average of 5 determinations. I = ± *S.D.*

iodine-131-labelled human growth hormone precipitated by comparison with the standard curve.

In 9 assays, the mean difference (± *S.D.*) in the percentage precipitation of iodine-131-labelled human growth hormone in duplicate standards was found to be 1·0 ± 0·7, with a predicted variability at each standard level (Table 1).

When the percentage precipitation of iodine-131-labelled human growth hormone is converted into the concentration of human growth hormone in plasma samples by using the standard curve run in each assay, duplicate values in the same assay agree within 20 per cent on the average throughout the whole range of values

Table 2. Plasma Human Growth Hormone Concentrations during Insulin Tolerance Tests

Subject	Plasma human growth hormone concentration (mμg/ml.)					Blood glucose (mg%)				
	0 min.	20 min.	40 min.	60 min.	90 min.	0 min.	20 min.	40 min.	60 min.	90 min.
P. B.	1·2	1·5	16·5	44·0	60·0	105	28	52	50	66
	1·0	1·0	19·5	48·0	62·0					
G. B.	15·5	35·0	56·0	8·0	24·0	86	36	45	73	72
	8·0	32·5	64·0	10·0	20·0					
L. C.	2·5	3·4	3·0	8·0	3·0	113	66	66	94	102
	6·0	3·8	6·0	9·0	3·5					

Plasma human growth hormone concentrations obtained during three insulin tolerance tests are seen in Table 2.

Excellent agreement has been found in low, medium and high ranges between the values of plasma human growth hormone obtained by the double antibody method and by the chromatoelectrophoretic method of Glick *et al.*[8] at present in use in our laboratory. The double antibody method moreover offers two distinct advantages: greater sensitivity can be obtained for a given specific activity of iodine-131-labelled human growth hormone and all manipulations in this procedure can be carried out at room temperature.

We thank Dr. William H. Daughaday for his advice and assistance.

THREE DEGREES OF GUANYLIC ACID — INOSINIC ACID PYROPHOSPHORYLASE DEFICIENCY IN MOUSE FIBROBLASTS

By Dr. JOHN W. LITTLEFIELD

John Collins Warren Laboratories, Huntington Memorial Hospital of Harvard University,
Massachusetts General Hospital, Boston, Mass.

LOSS of the enzyme guanylic acid–inosinic acid pyrophosphorylase confers resistance to the analogue 8-azaguanine in bacteria and mammalian cells[1]. In the latter this loss might be expected to be step-wise, reflecting gene dosage, and recently sub-lines of mouse fibroblasts (*L* cells) partially deficient in pyrophosphorylase activity and partially resistant to this analogue have been described[2]. Further investigations now suggest that there are three degrees of enzyme deficiency and resistance to 8-azaguanine in these aneuploid cells.

Cell culture methods were the same as those used previously[2] except that the medium containined 10 per cent fœtal calf serum (Microbiological Associates, Inc.), rather than calf serum. Chromosomes were enumerated by standard methods[3,4] after the cells were exposed for 16 h to colchicine (5 × 10^{-6} M). The pyrophosphorylase activity of cell extracts was determined with hypoxanthine-8-^{14}C as before[2], except that the reaction mixture was incubated at 37° C for 1 h, rather than at room temperature for 2 h. A factor relating these two conditions was determined; and to allow comparison with previous investigations, all results are expressed as c.p.m./μg of cell extract protein per 2 h at room temperature. In certain assays, guanine-8-^{14}C (1 μc./m.mole; 7 × 10^{-5} M) (Schwarz Bioresearch Inc.) was used in the reaction mixture instead of hypoxanthine-8-^{14}C.

The specific activities of guanylic acid–inosinic acid pyrophosphorylase in extracts of 38 sub-lines of *L* cells are shown in Fig. 1. The average activity of wild-type cells was 332 ± *S.E.* 11 c.p.m./μg protein in 9 extracts during a 2-year period. Three clonal derivatives (*A*19, *A*23 and *A*24) were in the same range. At the bottom of Fig. 1 are shown the activities of cloned or uncloned lines highly resistant to 8-azaguanine, which were selected with 1·0–2·0 μg of 8-azaguanine/ml. as described previously[2]. The average enzyme activity in extracts of these lines was 1 per cent of wild-type activity.

Lines of *L* cells moderately resistant to 8-azaguanine were obtained in two ways[2]. In suspension culture 3 uncloned populations (*A*70*M*, *A*100*M* and *A*110*M*) were selected with 0·1 μg of 8-azaguanine per ml. In Petri dishes 2 clonal lines (*A*41 and *A*46) were selected with 0·1–0·3 μg of 8-azaguanine/ml.; afterwards one of these lines was recloned once (*A*46–3) and again (*A*46–3–6 and *A*46–3–7). The average activity of these 8 lines was 113 ± *S.E.* 8 c.p.m./μg protein.

The activities of these moderately resistant lines were not statistically separable from those of two revertant populations (*A*55*R* and *A*63*R*) and 3 clonal derivatives thereof[2] (average activity 116 ± *S.E.* 11 c.p.m./μg of protein). Altogether the activities of these 13 lines averaged 35 per cent of wild-type activity.

When on two occasions wild-type cells in suspension culture were exposed to an even lower concentration of 8-azaguanine (0·01 μg/ml.), cell multiplication was not inhibited. However, after growth for approximately

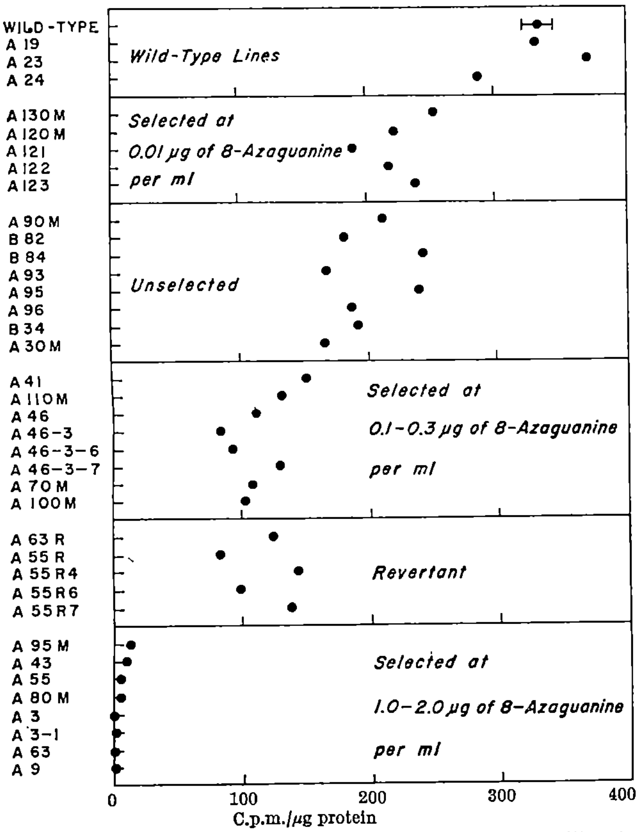

Fig. 1. The guanylic acid–inosinic acid pyrophosphorylase activities of 38 cell lines. As indicated, certain lines were obtained by selection of wild-type cells with 0·01, 0·1–0·3 or 1·0–2·0 µg of 8-azaguanine per ml. All lines were clonal except wild-type, *A55R* and *A63R*, and those lines designated with the suffix *M*. Cell extracts were prepared and assayed as described in the text and previously (ref. 2). The points represent the assay in duplicate of a single extract of a line, or the average activity of several extracts. For wild-type cells nine extracts assayed over a 2-year period averaged 332 ± *S.E.* 11 c.p.m./µg protein

2 months with the analogue, the pyrophosphorylase activity of cell extracts (*A*120*M* and *A*130*M* in Fig. 1) was decreased in comparison with untreated wild-type cells assayed at the same time. It was not possible to select lines of this sort as clones in Petri dishes, presumably because these cells were almost as sensitive to 8-azaguanine as wild-type cells. However, one of these lines was cloned to exclude the possibility that it was a mixture of wild-type and moderately or highly resistant cells; extracts of these clonal derivatives (*A*121, *A*122 and *A*123) were again less active than wild-type extracts. The average activity of these 5 lines was 221 ± *S.E.* 10 c.p.m./µg of protein, or 67 per cent of wild-type activity. Thus these lines were intermediate in regard to resistance and enzyme content between wild-type cells and the 13 moderately resistant lines described above.

Furthermore, after continuous growth for a number of months, untreated wild-type cells were found to contain less enzyme than previously. These cells (*A*30*M*) were discarded, and a new culture begun from a frozen sample of the original common stock which had been maintained previously in more complete medium in another laboratory[5]. The new cells were as active as before, but again after several months their activity had declined (*A*90*M*). In neither case had the generation time appreciably shortened. Several clonal derivatives of both *A*30*M* and *A*90*M* (*A*93, *A*95, *A*96, *B*34, *B*82 and *B*84) also contained less enzyme activity. The average activity of these 8 'unselected' lines was 197 ± *S.E.* 10 c.p.m./µg of protein.

The activities of the 5 lines selected at 0·01 µg of 8-azaguanine/ml., and the 8 'unselected' lines, were not statistically separable, and together averaged 63 per cent of the activity of wild-type cells. This group was statistically distinct (Student's *t* test yields $P < 0{\cdot}001$) both from wild-type cells and from the moderately resistant lines described above.

In mammalian cells it is likely that guanylic acid and inosinic acid are pyrophosphorylated by the same enzyme[1], although Kalle and Gots[6] have presented evidence that this may not always be the case in *Salmonella typhimurium*. We determined the pyrophosphorylase activity of extracts of 12 lines with both guanine-8-^{14}C and hypoxanthine-8-^{14}C. The results, calculated for both radioisotopes as a percentage of the activity of wild-type cells, are shown in Table 1. Although the results with guanine-8-^{14}C are consistently slightly higher than those with hypoxanthine-^{14}C, both radioisotopes gave the same ordering of lines in regard to pyrophosphorylase activity, as if guanylic acid and inosinic acid were substrates for the same enzyme in *L* cells.

Chromosome counts were performed on a number of the cell lines described above. The average of all counts was 53 ± *S.E.* 0·9. More detailed karyotype analyses[3,4] have not been carried out.

It was possible to estimate the frequency of moderately or highly resistant cells in various lines from the day of appearance and generation times of such cells in cultures exposed to 0·1 or 1·0 µg of 8-azaguanine/ml.[2]. The frequency of moderately resistant cells in the wild-type culture was approximately 1·6 and $0{\cdot}4 \times 10^{-3}$ on two occasions. In single experiments the approximate frequency of highly resistant cells was 3×10^{-2} in a moderately resistant culture, 3×10^{-4} in a slightly resistant culture, and 10^{-5} in a wild-type culture[2].

These results indicate that in *L* cells three statistically distinct degrees of loss of guanylic acid–inosinic acid pyrophosphorylase activity can be distinguished, leaving an average of 63, 35 and 1 per cent of wild-type activity. Previous investigations suggested that these cells contained a decreased amount of active enzyme, rather than an unchanged amount of enzyme of altered kinetic properties[2]. The synthesis of this enzyme cannot be 'de-repressed'[2]. Therefore, it might be expected to be present in proportion to gene dosage. While the chromosome number of normal mouse cells is 40, that for several *L* cell lines averaged 53. It may be that in these cells there are usually 3 homologous chromosomes (trisomy) with the pyrophosphorylase locus. The 3 degrees of enzyme deficiency may reflect the inactivation of 1, 2 or 3 such loci, or the loss of 1, 2 or 3 such chromosomes.

The decreasing frequency of highly resistant cells in moderately resistant, slightly resistant and wild-type cultures is in accord with this concept. Moreover, the frequencies in wild-type cultures of highly resistant (10^{-5}) and moderately resistant (10^{-3}) cells suggest that the loss of one pyrophosphorylase locus to produce slight resistance, the frequency of which cannot be determined directly, is an even more common event. There are other examples of changes in drug resistance in *L* cells which are frequent and may involve only one chromosome: the acquisition of high resistance to puromycin[7], reversion in 2 lines highly resistant to 8-azaguanine[2], and the acquisition of partial resistance to 5-bromodeoxyuridine[8]. Similarly frequent changes occurred in an established line of human bone marrow cells[9].

Table 1. PYROPHOSPHORYLASE ACTIVITY DETERMINED WITH HYPOXANTHINE-8-^{14}C AND GUANINE-8-^{14}C

Cell line	Wild-type specific activity (per cent) Hypoxanthine-8-^{14}C	Guanine-8-^{14}C
Wild-type	100 (90–110)	100 (89–108)
*A*24	109	108
*A*90*M*	68	71
*A*120*M*	67	74
*A*41	52	66
*A*110*M*	40	61
*A*55*R*7	38	46
*A*46	33	40
*A*100*M*	31	48
*A*95*M*	4	9
*A*55	1	3
*A*3–1	0	1

The wild-type activity represents the average activity of four extracts.

Rather than mutation, these changes probably reflect the large number of mitotic abnormalities in aneuploid lines[4,10,11], including uneven distribution of chromosomes to daughter cells as well as intrachromosomal rearrangements. Indeed, Szybalski has been unable to demonstrate mutagenesis in an aneuploid line with a number of agents known to be mutagenic in bacteria, and has suggested that this may be because of the high frequency of mitotic abnormalities[12].

A change in one chromosome with a pyrophosphorylase locus seems to have occurred also in the wild-type population during growth under new conditions (the 'unselected' lines in Fig. 1). This is analogous to the shifts in karyotype observed by Hsu[10]. The new genotype was presumably advantageous for cell survival, perhaps due not so much to the loss of a pyrophosphorylase locus as to the loss of an unknown linked locus. If this genotype occurred frequently, as discussed here, it need have produced only a slight shortening of the generation time, or other advantage, to replace the original wild-type cells during growth for several months.

BIOSYNTHETIC LABELLING OF MAMMALIAN INSULINS *IN VITRO*

By Dr. K. W. TAYLOR and D. G. PARRY
Department of Medicine and Diabetic Department, King's College Hospital, London

AND

G. HOWARD SMITH
Wellcome Research Laboratories, Beckenham, Kent

INCORPORATION of labelled amino-acids into insulin is now being examined for information it may give on the synthesis of a protein of known structure. Attempts have been made to label insulin *in vivo* by Voelker *et al.*[1] but, because of their greater convenience, most other workers have used methods of labelling *in vitro*, using for this purpose ox or calf pancreas[2–4], rat pancreas[5], or giant islet tissue from teleostean fish[6,7]. In mammalian pancreas, however, a very rapid incorporation of labelled amino-acids also takes place into the proteins of acinar tissue, and the presence of so much other labelled protein makes for great difficulties in isolating insulin in a state of radiochemical purity. In the rat, a further difficulty is in the presence of two insulins, differing in structure and properties[8].

It will be shown here that insulin is labelled by a process which is compatible with synthesis, when either fresh ox pancreas or rat pancreas is incubated with tritium labelled amino-acids.

Incubation of pancreas and purification of insulin. A satisfactory medium for incubation of pancreas with amino-acids appeared to be a bicarbonate buffered saline solution[9], to which glucose had been added to give a concentration of 250 mg/100 ml. After incubation, the isolation of insulins, or peptides derived from labelled insulins, proved to be a major problem and, even after very exhaustive extraction procedures, it proved very difficult to get rid of radioactive contaminants. Similar problems have been reported by Humbel[7], in the purification of labelled toadfish insulins. In all the isolation procedures used, insulins were first extracted by acidified ethanol, and a procedure based on that of Best *et al.*[10]. After removal of salts, the crude insulin was first purified by paper chromatography. This by itself proved inadequate in our hands for isolation of either ox or rat insulins in a state of radiochemical purity. With rat insulins further purification was achieved after paper chromatography, and elution from paper, by repeated isoelectric precipitation in the presence of carrier insulin[11]. Some similar considerations also applied to the purification of *A*- and *B*-chains derived from rat insulins. It was found that purification of these from radioactive contaminants was best achieved by paper electrophoresis at *p*H 2 in 5 M formic acid. These difficulties have been discussed at length elsewhere[11].

One possible way in which the high degree of radioactive contamination of insulin labelled *in vitro* may be avoided is by the use of immunological methods to isolate the insulin. After incubation of pancreas with tritiated leucine, radioactive insulin was precipitated using antibody by methods which have already been outlined, the insulin being regenerated with acid, and then purified by paper chromatography[12]. Such insulin appeared to be homogeneous on electrophoresis (Fig. 1).

Incorporation into insulins. In both rat insulins, leucyl residues are present in both *A*- and *B*-chains, though isoleucine is confined to the *A*-chain of each (Smith, L. F., personal communication). Accordingly, if labelling of the insulin proceeds by protein synthesis, both chains should be labelled when pancreas is incubated with leucine. Rat pancreas was accordingly incubated with tritiated leucine or isoleucine, and after addition of carrier ox insulin, *A*- and *B*-chains were made from it by the method of Sanger[13]. After electrophoresis on paper, only *B*-chain which had been derived from pancreases incubated with leucine was labelled[11]. This suggested that labelling is in accord with the structure of the insulins. In addition, the distribution of label among amino-acids obtained by the hydrolysis of labelled rat insulins suggested that neither leucine nor isoleucine was metabolized by rat pancreas in such a way as to give rise to significant amounts of radioactivity in other amino-acids[11].

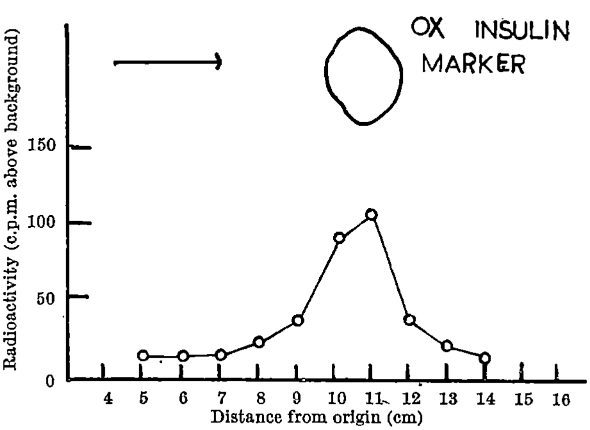

Fig. 1. Distribution of radioactivity on paper after electrophoresis of insulin labelled with tritium and purified by antibody precipitation. Ox insulin was labelled *in vitro*, and after chromatography of an insulin extract precipitated with antibody, an appropriate area of paper was cut out and sewn on to a second strip of paper for electrophoresis at *p*H 2, in formic acid. Radioactivity was determined on strips of paper as shown

Table 1. INCORPORATION OF TRITIATED LEUCINE INTO INSULIN AND OTHER PROTEINS OF OX PANCREAS *in vitro*

	Conc. of glucose in medium 25 mg/100 ml.	250 mg/100 ml.
* Radioactivity in proteins of acid–ethanol extract of pancreas (c.p.m./g wet pancreas × 10^{-4})	2·8 ± 0·67	3·4 ± 0·51
Specific activity of insulin (c.p.m./μg of insulin)		
Exp. 1	0·91	2·10
2	0·62	1·91
3	0·03	0·48
†4	0·14	1·30

* Mean of four results, ± *S.E.M.*

† Insulin purified by both chromatography and electrophoresis.

Pancreas was incubated with tritiated leucine and after extraction with acid ethanol, insulin was precipitated with antibody. Insulin was then regenerated from the precipitate and purified by chromatography. Insulin was assayed by elution of dyestuff. Concentration of radioactivity was different in the two groups of experiments.

Evidence that ox insulin was being labelled has been obtained by differential labelling of the *A*- and *B*-chains. Using a mixture of amino-acids of high specific activity (^{14}C-leucine, 160 mc./m.mol, and tritiated isoleucine, 315 mc./m.mol), it could be shown that the ratio of leucine to isoleucine was obtained for labelled material which was compatible with the known distribution of leucine and isoleucine in the molecule. Moreover, agents such as 2,4-dinitrophenol or puromycin, which are agents known to inhibit protein synthesis, characteristically reduce incorporation into ox insulin *in vitro*[14]. Labelling of both rat and ox insulin appears, therefore, to be by a biosynthetic mechanism.

Effect of glucose concentration on incorporation into insulin. Incorporation of leucine into insulin appears to be greatly enhanced by increasing the glucose concentration from 25 mg/100 ml. to 250 mg/100 ml. (Table 1). By contrast, only a very small effect of varying the glucose concentration on incorporation of leucine into a crude acid alcohol extract of ox pancreas was found, and it was not statistically significant. A similar lack of effect of variations in glucose concentration on incorporation of leucine into toadfish pancreas has also been reported[15]. It is not at present known whether this effect on incorporation is confined to ox insulin or is a widespread phenomenon in the pancreas of other species. If this should be the case, effects of glucose on incorporation into insulin might be of considerable physiological significance, perhaps as a regulatory mechanism for controlling the quantity of insulin stored in pancreas. A direct connexion has been suggested by Haist[16] between the blood glucose-level and the amount of insulin which is extractable from the pancreas of rats.

In summary, it is concluded that segments of mammalian pancreas, incubated *in vitro*, may be used for an investigation of factors which affect incorporation into insulin, though special purification methods have to be used to ensure radiochemical purity. A high concentration of glucose in the incubating medium appears to be important in achieving a rapid rate of incorporation into insulin in these experiments.

We thank the Medical Research Council for a grant to one of us (K. W. T.) as well as the British Diabetic Association and British Insulin Manufacturers for financial assistance towards this work. We also thank Dr. Clifford Hoyle and Dr. Wilfrid Oakley for help with facilities as well as much encouragement in the course of the work.

ENERGY TRANSFER IN PROTEINS

By LEROY AUGENSTEIN and JAYANTI NAG-CHAUDHURI*

Biophysics Department, Michigan State University, East Lansing

A NUMBER of workers have reported that when proteins or amino-acid mixtures containing tryptophan are excited with ultra-violet light in the range 250–300 mμ, the fluorescence emitted has many of the properties of that from the constituent tryptophan, whereas fluorescence typical of tyrosine arises from those proteins which contain tyrosine but no tryptophan (an extensive review of the original literature can be found in ref. 1). Further, Steele and Szent-Györgyi reported that the wave-length of maximum phosphorescence from tryptophan-containing proteins is the same as that for phosphorescence from tryptophan[2]. On this basis, it has often been concluded that in proteins an excited phenylalanine will transfer its energy to either tyrosine or tryptophan residues nearby and an excited tyrosine will either transfer its excitation to a neighbouring tryptophan or be quenche without emitting[3–5]. Evidence that intra-protein energy transfer is probably efficient and occurs via a so-called resonance transfer mechanism has been reviewed by various authors[1,6]. However, Weber and Teale calculated from the fluorescence excitation spectra of many tryptophan-containing proteins that energy transfer from tyrosine to tryptophan probably occurred with only very low efficiency[7]. Also, since 1960 several workers have reported finding a weak tyrosine fluorescence component in proteins containing both tyrosine and tryptophan[8–10]. Furthermore, there has been a recent abstract reporting phosphorescence characteristic of tyrosine from some proteins which also contain tryptophan[11].

Accordingly, it seems worth while to report here experiments which raise further questions about the efficiency of transfer from tyrosine to tryptophan as well as about the nature of the electronic states of tyrosine residues in proteins. That is, in accord with Longworth's recent report, phosphorescence characteristic of that from tyrosine can be readily detected from tryptophan-containing proteins such as trypsin, bovine plasma albumin, alcohol dehydrogenase, pepsin and pepsinogen. However, 'tyrosine' phosphorescence is not observed from all tyrosine-containing proteins—for example, none could be detected from either chymotrypsin or chymotrypsinogen. Further, only slight evidence of tyrosine fluorescence can be found in any of these proteins. This report is concerned primarily with the investigations of phophorescence.

To prepare the solutions for spectroscopy, 10-mg portions of either a highly purified crystalline sample of tyrosine, or tryptophan, or one of a number of proteins was dissolved in 25 ml. of water. To these solutions was added sufficient glucose (0·5 per cent) or spectral grade ethylene glycol (1 : 1 by volume) to minimize the formation of microcrystals during cooling to liquid nitrogen temperature. The phosphorescence spectra shown in Fig. 1, obtained at 77° K in an Aminco spectrophosphorimeter[12], are representative of the data derived. There it can be seen that, on excitation at 280 mμ for tryptophan and both the proteins, the maximum phosphorescence is observed at 435 mμ and there are obvious shoulders at 410 and 460 mμ. However, the shortest wave-length of phosphorescence observed from both proteins (345 mμ) agrees with that from tyrosine: the short-wave-length portion of the alcohol dehydrogenase phosphorescence spectrum is quite obviously unlike that from tryptophan and seems to mimic that from tyrosine both in shape and the shortest wave-length observed. Further, the decay times measured at 380 mμ agree with those for tyrosine whereas the decay observed at 480 mμ is dominated by a component which decreases at the same rate as tryptophan: at intermediate wave-lengths the decay curves appear to be a mixture of these two components having respective decay times of 1–2 and almost 6 sec. (See discussion in ref. 13 of the effect of intramolecular environments on phosphorescent decay times.)

---

* Present address: Department of Biophysics, All India Institute of Medical Science, Ansari Nagar, New Delhi 16.

Assuming that the shapes of the phosphorescence emission spectra for constituent tyrosine and tryptophan residues are the same as those shown in Fig. 1 for these two amino-acids in a glass, it can be estimated that approximately 0·5 of the phosphorescence from alcohol dehydrogenase and 0·06 of that from trypsin arises from constituent tyrosine when excitation is by 280 mμ light (the maximum absorption of both tyrosine and tryptophan is near 280 mμ). Furthermore, it is estimated that tyrosine accounts for almost 0·7 of the phosphorescence emitted when alcohol dehydrogenase is excited by 240 mμ light (that is, primarily excitation of phenylalanine): the peak at about 400 mμ is almost equivalent in intensity to the usual maximum at 435 mμ.

It seems unlikely that the phosphorescence in the interval 350–390 mμ arises from tyrosine contamination in the protein samples, inasmuch as the crystalline protein preparations which were of the highest purity available commercially were further purified by passage through a 15-cm 'Sephadex' column. Preliminary results with the seven proteins listed also indicate that the intensity of tyrosine phosphorescence relative to that from tryptophan cannot be correlated with the ratio of tyrosine/tryptophan content nor with the absolute number of tyrosine or tryptophan residues in the various proteins.

Unequal distribution of tyrosine and tryptophan residues within a given protein could result in large yields of emission from tyrosine residues which might be sufficiently isolated—either because of distance or mutual orientation—from potential acceptor tryptophans so that resonance transfer of excitation energy is unlikely. However, it would be expected that, if this were an important cause of the observed results, then in addition to the phosphorescence a significant amount of tyrosine fluorescence should be detected also, since a fluorescence/phosphorescence ratio of approximately 1 has been recorded from tyrosine in glasses[13]. Although resolution near the peak of tyrosine fluorescence at 300 mμ is made difficult by Rayleigh scattering of the 280 mμ exciting light from the frozen (cracked) solutions, the amount of fluorescence which would be expected from 'isolated' tyrosines has not been observed. Further, excitation with wave-lengths less than 260 mμ permits adequate separation of fluorescence and scattered light to show that, in fact, only a minimal fraction of the fluorescence emitted from alcohol dehydrogenase is typical of that from tyrosine.

The present results indicate that interactions with neighbouring residues in proteins so distort the electronic properties of tyrosine residues that their normal emissive, and thus energy transfer, properties are drastically altered. In this regard, previous investigations of the wave-length corresponding to maximum phosphorescence, the F/P ratio and the kinetics and lifetimes of phosphorescence decay, indicated that approximately three of the six tyrosines in RNase interact strongly with neighbouring residues[13]. In fact, Weber suggested that the low efficiency of tyrosine fluorescence was a result of quenching arising from interaction of the phenolic OH groups with neighbouring carboxylate moieties[9].

The variation in relative tyrosine emission among the proteins investigated indicated that either: (*a*) all tyrosines are sufficiently perturbed so that practically all fluorescence is quenched, but the interactions of some residues are such that phosphorescence can still occur; or (*b*) most tyrosine residues are relatively unperturbed but the interactions of a few are sufficiently strong so that inter-system crossing from singlet to triplet configurations competes both with tyrosine fluorescence and with resonance transfer to tryptophan.

Precise measurements of quantum yield as a function of exciting wave-length, as well as better resolution of emission lifetimes, are needed to select among these two possibilities. Even so, it seems worth while considering possibility (*b*) further since the great increase of tyrosine phosphorescence relative to that from tryptophan, when phenylalanine is preferentially excited (by 240 mμ light), suggests that, at least in alcohol dehydrogenase, perturbations of tyrosine inter-system crossing may be very important.

Approximately equal fluorescence and phosphorescence are observed when tyrosine is excited at 77° K in an organic glass. Thus, in relatively unperturbed tyrosine residues the rate constant for intersystem crossing must be essentially equivalent to that for fluorescence. Accordingly, in a protein in which all tyrosines are unperturbed, no tyrosine emission would be anticipated, since the relative rate constants for energy transfer should be about two orders of magnitude greater than the rate constant for fluorescence emission. That is, fluores-

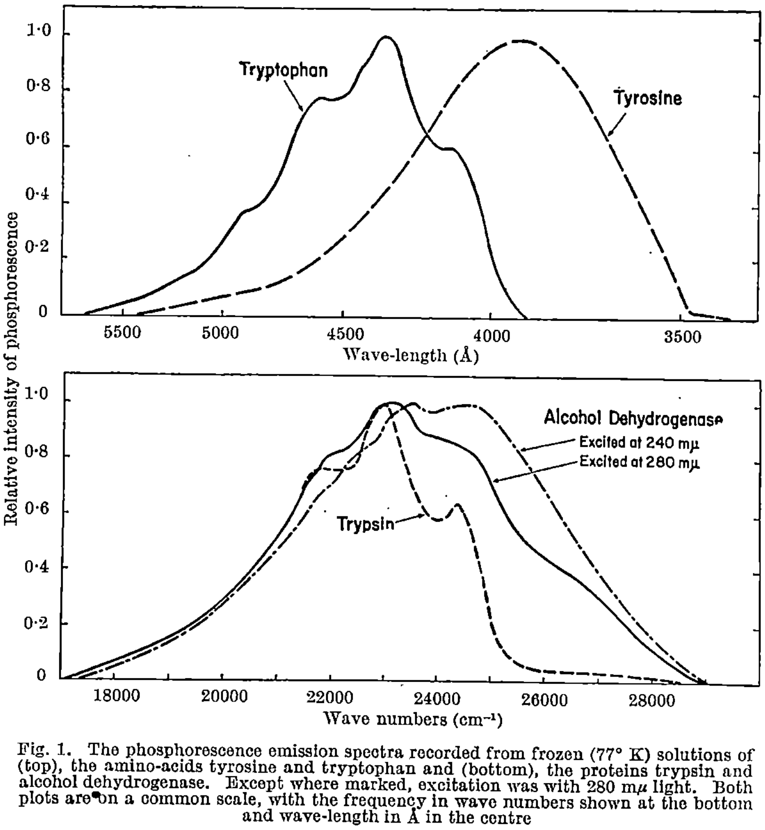

Fig. 1. The phosphorescence emission spectra recorded from frozen (77° K) solutions of (top), the amino-acids tyrosine and tryptophan and (bottom), the proteins trypsin and alcohol dehydrogenase. Except where marked, excitation was with 280 mμ light. Both plots are on a common scale, with the frequency in wave numbers shown at the bottom and wave-length in Å in the centre

çence lifetimes are normally about 10^{-9} sec, whereas the conditions of resonance required for Förster-type energy transfer from tyrosine to tryptophan are presumed to occur in 10^{-12}–10^{-11} sec during vibrational relaxation[6]. Indeed, there are some proteins containing tyrosine in which only tryptophan emission is observed. By contrast, in those proteins where significant levels of tyrosine phosphorescence are observed, it would be concluded that the interactions of tyrosine with neighbouring residues are such that the rate constant for inter-system crossing is increased to a value comparable to that for vibrational relaxation. Such a large perturbation could presumably be the result of heavy atom contamination[14] or perhaps more probably the strong interaction between tyrosine and neighbouring disulphide groups (spin-orbit coupling and/or charge transfer)[15]. In this respect, interactions between aromatic residues and cystine have been postulated to account for the disruption of specific cystine residues during protein inactivation by ultra-violet irradiation[16,17].

COMBINATION WITH RED CELLS OF IMMUNE RABBIT 7S ANTIBODY AND ITS SUB-UNITS

By DR. C. L. GREENBURY, D. H. MOORE and DR. L. A. C. NUNN

Department of Pathology, Stoke Mandeville Hospital, Aylesbury, Buckinghamshire

WE have shown[1], in the case of immune rabbit anti-blood group *A* antibodies, that 7*S* γ-antibody is a much less efficient agglutinating agent than 19*S* ($\beta_2 M$) antibody: that is to say that at the end point of a hæmagglutination titration with human group A_1 red cells, each cell is carrying 19,500 molecules in the case of 7*S* antibody, and only 25 molecules in the case of 19*S* antibody. We have also shown that the mean distance separating *A*-antigen sites on the red cell is only about half the length of a 7*S* molecule. Even supposing uniform distribution of *A*-sites on the cell there must be approximately 18 sites within a circle radius 240 Å (the length of a 7*S* molecule). In these circumstances, if there were no steric impediment, it would seem most likely that the free combining site of an antibody molecule already bound to a red cell by one of its specific groups would also attach itself to the same red cell. Molecules so attached could not take part in agglutination; conversely if, as we believe, 19*S* antibody is multivalent it is unlikely that all the specific groups on one molecule could be attached to a single red cell.

In order to throw further light on this question we have investigated the reactions with red cells of fragments derived from immune rabbit anti-A 7*S* antibody by means of papain digestion and pepsin digestion followed by reduction with cysteine or 2-mercaptoethylamine with subsequent blocking of the free —SH groups with iodoacetate. This treatment results in the production from each 7*S* antibody molecule of two univalent fragments which retain the antibody specificity of the original molecule[2-4]. We find that treatment with cysteine and iodoacetate is, in the present context, without effect on intact 7*S* antibody.

The binding constant (*K*) of the reaction between an antibody and antigen can be expressed as the reciprocal of the concentration of antigen (red cells in this case) at which half the antibody is combined, if the concentration of antibody is sufficiently low for the combined antigen to be a small fraction of the total antigen. Aliquots of iodine-131-labelled antibody preparations pre-absorbed with O-cells and diluted in bovine albumen have been added to varying quantities of centrifuged A_1 red cells. The red cells have been resuspended and, after allowing 30 min for the reaction with antibody to take place, the supernatant has been removed and the amount of antibody adhering to the red cells has been measured in a scintillation counter[1]. By suitable techniques it has been possible to avoid the necessity of washing the red cells, which would involve the elution of unavid antibody. Curves, of which Fig. 1 is typical, have been constructed from which the concentration of red cells necessary to absorb half the antibody has been measured.

In plotting these curves, the total antibody available has, in the case of intact 7*S* antibody and 5*S* peptic digest (which is bivalent), been taken as that amount absorbed by 16 per cent cells. It is clear from the asymptotic shape of the curves that the error in this assumption is small. It has been assumed that reduction of peptic digest has not destroyed any antibody and that the reduced preparations contain the same proportion of antibody radioactivity as the 5*S* peptic digest from which they were derived. The shape of the curves, which are still rising steeply, lends

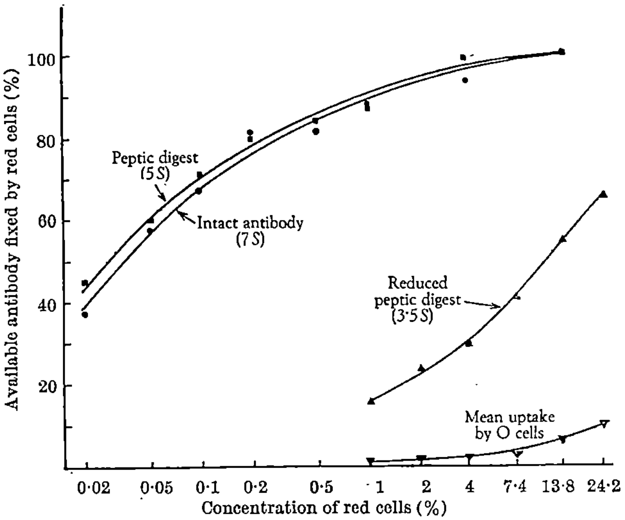

Fig. 1. The uptake by A_1 and *O* red cells of antibody preparations

support to this assumption. For papain digest we have assumed that the active fragments are the same as those produced by reduction of peptic digest[3] and that the proportion of radioactivity absorbable is the same as that in the whole (before dialysis) peptic digest of the $7S$ preparation.

Comparisons have been made of the $7S$ antibody (separated by DEAE-cellulose chromatography) and its derivatives from three rabbits, all the derivatives from one serum being investigated simultaneously. In each case, the curves for $7S$ antibody and peptic digest have been almost identical. The curves for univalent fragments, however derived, have been very close together and parallel. The concentrations of A_1 cells necessary to absorb half the antibody from $7S$ or $5S$ preparations from each of the three rabbits were, respectively, 0·16, 0·03 and 0·02 per cent; the cell concentrations required to absorb half the univalent antibody derived from these preparations were, respectively, 19, 10·5 and 6 per cent. That is to say $\frac{K \text{ bivalent } Ab \text{ } (7S \text{ or } 5S)}{K \text{ univalent } Ab \text{ fragments}}$ was 119, 350 and 300 respectively for the three rabbit sera.

The greatly diminished binding constant of univalent antibody fragments could be explained if the process of splitting the molecule had distorted the antibody specific group; this seems unlikely since, at least for a small hapten, K remains unaltered after splitting the antibody molecule[5]; moreover, if the binding constant of antibody sites were drastically diminished it seems improbable that a comparatively small excess of univalent fragments would inhibit precipitation in the ovalbumin – anti-ovalbumin system[2]. Labelling with iodine does not appear harmful since labelled anti-ovalbumin fragments which we have prepared inhibit precipitation in the same proportion as described by Porter. It is possible that reduction in the size *per se* of the antibody would reduce K by eliminating some non-specific binding of the antibody molecule, but we find no difference in K between the $7S$ and the bivalent $5S$ fragment derived therefrom.

We consider that the great diminution in binding constant which accompanies the reduction of antibody valency from 2 to 1 gives support to our hypothesis that rabbit immune $7S$ anti-A antibody mostly combines with the red cell by both its specific groups. The possibility of this type of antigen–antibody attachment does not appear to have received consideration and is even excluded from his calculations by Goldberg[6], although it is not necessary to postulate that the bivalent attachment of antibody on a red cell is to a single antigen molecule. However, Almeida, Cinader and Howatson[7] have shown electron micrographs which may be interpreted as bivalent attachment of a single antibody molecule to a wart virus particle.

A final resolution of this point may be possible by the examination, which we are about to attempt, of univalent fragments recombined to the bivalent $5S$ form[8], where if our hypothesis is correct, recombined pure antibody should regain its $5S$ binding constant, whereas $5S$ recombinants made up of one antibody and one non-antibody $3·5S$ fragment would have the binding constant of a univalent fragment.

QUINACILLIN: A COMPARISON WITH OTHER PENICILLINASE-RESISTANT PENICILLINS

By DR. J. T. SMITH, DR. J. M. T. HAMILTON-MILLER and PROF. R. KNOX
Department of Bacteriology, Guy's Hospital Medical School, London, S.E.1

QUINACILLIN, 3-carboxy-2-quinoxalinylpenicillin, a recently described semi-synthetic penicillin, was found[1] to have 'unusual properties', namely, antibacterial activity highest against *Staphylococcus aureus*, enhancement of antibacterial activity and rate of diffusion in agar with decrease in pH of the medium, and poor inducing ability for staphylococcal penicillinase. In view of these findings, we have examined the interactions of quinacillin with various bacteria and their penicillinases, and are able to confirm and extend the description of this penicillin as possessing "unusual properties".

Quinacillin as a substrate for penicillinase. (*a*) *Gram-positive bacteria.* The rates of hydrolysis of quinacillin at various concentrations in 0·025 M sodium phosphate buffer pH 7·4 were measured using the hydroxylamine method[2]. With staphylococcal penicillinase made, as previously described[3], from *Staph. aureus E*3, the Michaelis constant (K_m) for quinacillin was 61 mM (28 mg/ml.) with a $V_{\max}$ 8 per cent that of benzylpenicillin; at an initial concentration of 4·3 mM (2 mg/ml.) quinacillin was not appreciably hydrolysed by this preparation. Richards *et al.*[1], who used the iodometric method of assay at pH 6·5, found that the K_m value for staphylococcal penicillinase (Parker strain) was 5 mg/ml. and the $V_{\max}$ was 5 per cent that of benzylpenicillin. They also found no appreciable hydrolysis of quinacillin at lower concentrations.

Penicillinase preparations[4] from *B. cereus* and *B. licheniformis* were found to hydrolyse quinacillin (initial concentration 4·3 mM) at 11 and 13 per cent, respectively, of the rates at which they hydrolysed benzylpenicillin. Both these preparations had K_m values for quinacillin of about 54 mM.

(*b*) *Gram-negative bacteria.* Cell-free preparations made from *Pr. morgani G* (ref. 5), *Pr. rettgeri* 410, *K. aerogenes* 366 (ref. 6) and *E. coli 214T* (ref. 7) did not appreciably hydrolyse quinacillin (initial concentration 4·3 mM). A cell-free extract of *A. cloacae* 53 (ref. 6) hydrolysed quinacillin (4·3 mM) at about 7 per cent of the rate at which it destroyed benzylpenicillin (5·4 mM) and intact cells of this organism hydrolysed quinacillin at about one-seventh of this rate (Table 1). Disruption of this strain has been shown[6] to increase its hydrolytic activity towards benzylpenicillin 25 times. Thus it seems that quinacillin can pass the substrate accessibility barrier in this strain more readily than benzylpenicillin.

Quinacillin as an antibacterial agent. Minimum inhibitory concentrations of quinacillin were determined, by means of the tube test, for six strains of *Staph. aureus*, *E*3, 13137, 6637, 5974 (all of which produce penicillinase, the last three being resistant to methicillin and cloxacillin[8]), *E3T* and Oxford (benzylpenicillin-sensitive, penicillinase-negative strains). Two inoculum sizes were used, about 10^6 and about 10^2 viable units per tube. The results

Table 1. DESTRUCTION OF 2 PENICILLINS BY *A. cloacae* 53
(rates expressed as μg/min/10^9 cells /ml.)

	Intact cells	Disrupted cells	Ratio (to nearest whole number) of penicillinase activity of disrupted to intact cells (= 'permeability factor')

Table 4. INDUCING ABILITIES OF FOUR COMPOUNDS FOR PENICILLINASE OF *Staph. aureus* E3

	Concentration μg/ml. to give maximal induction	Concentration μg/ml. to give half maximal induction	Ratio of induced to basal penicillinase activity at maximum
Quinacillin	12·5	2·07	17·8
6-Aminopenicillanic acid *	10·0	3·0	16·3
Methicillin *	3·0	0·27	36·0
Cloxacillin †	0·1	0·013	71·3

* Ref. 3. † ref. 15.

(Table 2) show that there is cross-resistance between cloxacillin, methicillin and quinacillin, but it appears that resistant strains are slightly more susceptible to quinacillin than to the other two, at least using large inocula. The 'inoculum size effect' obtained with this series of organisms is probably a reflexion of populations that are not homogeneous, in that they contain small proportions of highly resistant bacteria[9]. In common with other penicillins, quinacillin was extremely poor at inhibiting the growth of *B. cereus*, the minimum inhibitory concentration being 5 mg/ml. for an inoculum of 10^6 organisms. Quinacillin was relatively inactive as an antibacterial agent against Gram-negative bacteria (Table 3). Richards *et al.*[1] also found that Gram-negative bacteria were resistant to quinacillin.

Quinacillin as an inducing agent for penicillinases. The ability of quinacillin to induce penicillinase production in *Staph. aureus E*3 was determined as described previously[3] and the results are shown in Table 4. It can be seen that the concentrations for half maximal induction ('induction constants'[10]) with quinacillin, methicillin and cloxacillin were 2·07, 0·27 and 0·013 μg/ml., respectively. Thus the 'induction constant' for quinacillin is some eight times larger than that for methicillin and 160 times larger than that for cloxacillin. In addition, as judged by the concentrations required for maximal induction and by the amount of enzyme production at these concentrations, quinacillin was a less effective inducing agent than either methicillin or cloxacillin. Using the Parker strain of *Staph. aureus*, Richards *et al.*[1] reported a twenty-five-fold difference between the 'induction constants' for methicillin and quinacillin, so, allowing for strain differences, it seems that quinacillin is a much poorer inducing agent than would be expected from its activity against penicillinase-producing staphylococci.

It appeared that the figures obtained here for quinacillin in induction experiments were very similar to those found for 6-aminopenicillanic acid in an earlier series of experiments[3]. To determine whether quinacillin was broken down to 6-aminopenicillanic acid (which could explain these similarities) during the process of induction, quinacillin was incubated at 37° C with washed cells from an overnight culture of *E*3 in phosphate-buffered saline at *p*H 7·4 for 3 h. The cells were centrifuged down, and enough of the supernatant fraction to contain approximately 50 μg quinacillin was applied to Whatman No. 1 paper and chromatographed in *n*-butanol 4 : acetic acid 1 : water 5, descending overnight; markers of quinacillin, the penicilloic acid derived from it (made by dissolving quinacillin in N soda, and neutralizing with N hydrochloric acid after 30 min at room temperature) and 6-aminopenicillanic acid were also applied to the chromatogram. When the run had been completed, the paper was dipped in 0·2 per cent ninhydrin in acetone[11], heated for 5 min at 100° C and then 'fixed' in alcoholic copper nitrate. Under these conditions, the quinacillin developed a pale-yellow colour, fluorescent in ultra-violet light (this yellow fluorescence could also be observed before ninhydrin treatment). The penicilloic acid developed a red colour which did not fluoresce. The R_F values of these two compounds in the solvent used were 0·82 and 0·65, respectively. No trace of a spot similar to that derived from 6-aminopenicillanic acid (R_F value 0·53—which develops a golden-yellow colour, slightly fluorescent[11]) could be observed in the incubation mixture. Nor was any evidence of a penicillin acylase obtained when the butyl acetate extraction technique[12] was used, with benzylpenicillin as substrate, with this strain of *Staph. aureus*. Hence, it appears that the resemblance between the values of certain induction parameters of quinacillin and 6-aminopenicillanic acid is a mere coincidence.

Quinacillin, benzylpenicillin, methicillin, cloxacillin and 6-aminopenicillanic acid were tested for inducing ability towards the penicillinase of *B. cereus*. Various concentrations of each inducing agent were dissolved in broth, 2 ml. of a 6-h 37° C culture of *B. cereus* 569 added to each 100 ml., and bottles were incubated overnight at 37° C. Portions were centrifuged (3,000*g* for 15 min), after mM *p*-chlormercuribenzoate had been added to prevent further induction, and the turbidity measured at 700 mμ. The supernatant fraction was adjusted to *p*H 7·4 with N sodium hydroxide and the rate of hydrolysis of benzylpenicillin estimated by the hydroxylamine method. Results were expressed in terms of the amount of increase in penicillinase activity as compared with a control culture grown in broth alone; Table 5 shows the results obtained. It is clear that quinacillin, although a better inducing agent than benzylpenicillin (probably due to its greater stability to this penicillinase), is not so efficient at the higher concentration as methicillin, cloxacillin or 6-aminopenicillanic acid.

Quinacillin did not cause any increased enzyme production in five strains of *K. aerogenes*—43, 370, 373, 407 and 414—nor in *K. ozaenae* 61; this is in common with the non-inducibility of these penicillinases by all other compounds tested[6]. When *Pr. morgani* 185 (ref. 5) and *Pr. rettgeri* 410 were grown overnight at 37° C in the presence of half the minimum inhibitory concentration of quinacillin, penicillinase was induced. The activities of these cultures after disruption, expressed in terms of μg benzylpenicillin hydrolysed/min/10^9 cells/ml., were 5·6 and 3·7, respectively. Uninduced preparations of these two organisms hydrolysed less than 0·1 μg benzylpenicillin/min/10^9 cell/ml.

Quinacillin as an inhibitor of benzylpenicillin hydrolysis by penicillinases. Penicillins which are only slowly hydrolysed by penicillinases have been shown to inhibit benzylpenicillin hydrolysis by *B. cereus*[13], *B. licheniformis*[11], *K. aerogenes*[14], *E. coli*[14] and *Pr. morgani*[14] penicillinase preparations. Mixtures of 1·3 mM (0·5 mg/ml.) benzylpenicillin and mM quinacillin were incubated with enzyme

Table 5. INDUCING ABILITIES OF FIVE COMPOUNDS FOR PENICILLINASE OF *B. cereus* 569

	Ratio of concentration of inducing agent to minimum inhibitory concentration for that inducing agent	
	1/10	1/4
Benzylpenicillin (1,250)	9	7
Quinacillin (5,000)	31	39
Cloxacillin (500)	21	54
6-Aminopenicillanic acid (10,000)	66	92
Methicillin (313)	25	140

Figures in brackets are minimum inhibitory concentrations of drugs for *B. cereus* (large inoculum, in μg/ml.).

Figures in body of the Table are enzymatic acitivity after induction, taking basal level = 1.

preparations from *Staph. aureus E*3, *B. cereus* 569 and *B. licheniformis*, which had been adjusted to hydrolyse 2 μg benzylpenicillin/min[11,15]. The rates of hydrolysis in the presence of quinacillin, measured by the hydroxylamine method, were compared with those obtained in the absence of quinacillin but no differences were observed. Hence, quinacillin, in contrast to the other poorly hydrolysed penicillins, does not inhibit any of the penicillinase preparations from Gram-positive bacteria examined.

When cell-free penicillinase preparations of *E. coli* 214*T* and *Pr. morgani* G were tested by the modified spectrophotometric method[11], no inhibition of the hydrolysis of benzylpenicillin (2·7 mM) could be detected in the presence of concentrations of quinacillin as high as 260 μM. However, under similar conditions 50 per cent inhibition of the penicillinase activities of *K. aerogenes* 366 and 373 was observed with 70 μM and 161 μM quinacillin, respectively; thus, quinacillin is about as active an inhibitor of the *Klebsiella* penicillinases as oxacillin and *BRL* 1577 (ref. 14). The fact that quinacillin does not inhibit the *E. coli* and *Proteus* penicillinase preparations is in contrast to the inhibitory action of other penicillins stable to the penicillinases of these bacteria.

Discussion. Richards *et al.*[1] found that quinacillin possessed unusual properties. We have confirmed that this penicillin is a poor inducing agent for staphylococcal penicillinase, and in addition we have shown that it is a relatively inefficient inducer of *B. cereus* penicillinase.

As a substrate for penicillinases derived from various sources, quinacillin shows in general a marked resistance to hydrolysis; its affinity for staphylococcal and Bacillus penicillinases was uniformly low, but it was hydrolysed rather more rapidly by the Bacillus enzymes. Penicillinase preparations from *K. aerogenes*, *E. coli* and *Pr. morgani* did not detectably destroy the compound, although a strain of *A. cloacæ* did hydrolyse quinacillin. An interesting feature of this penicillin is that it does not inhibit penicillinases from *B. cereus* and *B. licheniformis*, which is in contrast to the action of other poorly hydrolysed penicillins. Similarly, penicillinase preparations from *E. coli* and *Pr. morgani* were not inhibited by quinacillin, and it was found to be only a very weak inhibitor of *K. aerogenes* penicillinases.

The discovery that a penicillin which is a poor inducer of staphylococcal penicillinase can also be an effective antistaphylococcal agent discounts the correlation that has been made by some authors[15–18] between inducing ability and antibacterial activity for penicillinase-producing staphylococci. Until now penicillins which are biologically active against penicillinase-producing *Staph. aureus*, besides being resistant to hydrolysis by this enzyme, have also been found to be very good inducing agents and can markedly inhibit various penicillinases. It is interesting that although quinacillin does possess the first two characteristics it is not a particularly good inducing agent nor an efficient inhibitor of penicillinases.

We thank Boots Pure Drug Company, Ltd., for gifts of quinacillin.

A COMPARISON OF EFFECTS OF SOME CHEMOTHERAPEUTIC AGENTS AND THOSE OF X-RAYS ON THE REPRODUCTIVE CAPACITY OF MAMMALIAN CELLS

By Dr. ROGER J. BERRY*

Radiobiology Laboratory, Radiotherapy Department, Churchill Hospital, Oxford

WHILE chemotherapeutic agents have been extensively investigated for ability to 'cure' a wide range of transplanted tumours *in vivo*[1] and have less frequently been investigated qualitatively *in vitro* in cultures of mammalian cells[2], there has been a paucity of quantitative investigation of the effect on cell reproductive capacity of agents known to have clinical usefulness in palliation of human cancer[3,4]. The technique of clonal cell culture described by Puck *et al.*[5] by which macroscopically visible colonies can be grown *in vitro* from single mammalian cells has been extensively applied to the examination of effects of ionizing radiation (see Porter[6] for a representative list of references). It is only recently, however, that this method has been used to investigate the dose-response to a chemotherapeutic agent[7].

The present communication reports investigations of the dose-response relationship for the reproductive capacity of two strains of mammalian cells exposed *in vitro* to several commonly used anticancer drugs and compares these relationships with that for X-irradiation of the same cells.

The drugs used in these experiments were of the following types: (1) *Nitrogen mustard.* (*a*) 'HN3' (tri-(2-chloroethyl)-amine, 'Trillekamin', Crookes). (*b*) Mannitol mustard (Mannomustine dihydrochloride, 'Degranol', Chinon). (2) *Ethylene imine* ('Thio-TEPA', Lederle). (3) *Epoxide* ('Epodyl', I.C.I., 32865). (4) *Antimetabolite* (5-fluorouracil, Roche). All drugs were diluted with sterile normal saline to desired final concentrations immediately prior to addition to the growth medium.

The mammalian cell lines used were HeLa S-$3_{\text{oxf.}}$, an aneuploid derivative of human cervical carcinoma kindly supplied by Dr. C. E. Ford, Medical Research Council, Harwell, and re-cloned in this laboratory, and the mouse strain $L_{\text{oxf.}}$ fibroblast kindly provided by Dr. J. Paul, Department of Biochemistry, Glasgow, and re-cloned in this laboratory by Dr. A. H. W. Nias. They were grown in Medium 199 (Glaxo) supplemented with 5 μg/ml. amphotericin *B* ('Fungizone', Squibb), and for HeLa: 10 or 20 per cent freshly drawn human AB serum; for strain *L*: 2 per cent pooled calf serum (Oxoid) and 0·5 per cent 'Bacto-Peptone' (Difco) for stock growth and 10 per cent pooled calf serum for clonal growth.

The technique of clonal culture was modified only slightly from that of Puck *et al.*[5]; cells were trypsinized ('Bacto-Trypsin', Difco, 0·25 per cent in 0·3 per cent sodium citrate made isotonic with sodium chloride) from a stock bottle containing a nearly confluent sheet of cells. They were re-suspended in the appropriate medium and

---

* Helen Hay Whitney Fellow in Radiobiology, University of Oxford.

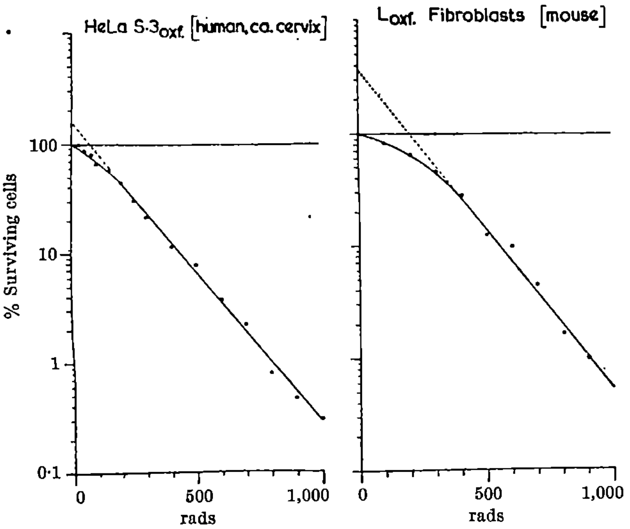

Fig. 1. Dose-response to X-rays, fraction of surviving cells (log scale) versus dose in rads (linear scale)

counted electronically (Coulter model *D*, 140μ orifice, calibrated previously against hæmacytometer count under phase microscopy). Appropriate dilutions were made and the cells were finally suspended in medium to which the drug under test had just previously been added in known concentration and 4 ml. aliquots were plated in 60 mm 'Falcon *TC*' polystyrene Petri dishes. The dishes were incubated in a humidified 5 per cent carbon dioxide–air environment at 37° C for 14 days to allow growth of visible colonies. If the drug given was stable for extended periods of time, it could be removed at any time by aspirating the medium, gently washing the plates with Medium 199 without serum, and then adding 4 ml. of the appropriate medium without the drug to each Petri dish. When cultures were to be irradiated, this was done 12–16 h after plating to allow the cells to attach firmly to the polystyrene dishes. Dishes were individually irradiated from below with 75 kVp X-rays (no additional filtration) at 15 cm FSD at a dose-rate of 140 rads/min; during irradiation 5 per cent carbon dioxide–air was circulated rapidly over each dish.

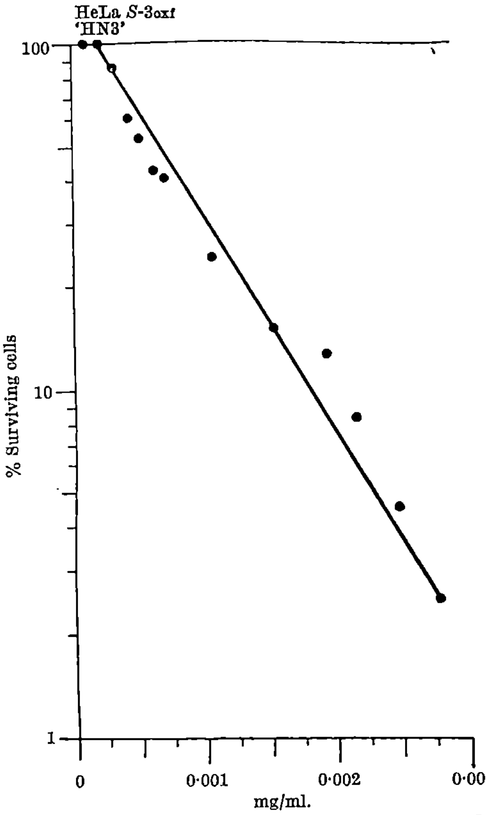

Fig. 2. Dose-response to nitrogen mustard 'HN3', HeLa *S*-3oxf. fraction of surviving cells (log scale) versus dose in mg/ml. (linear scale)

In all experiments, the number of cells plated was calculated so that the number of colonies produced was approximately 200 per dish. After 14 days' incubation, all dishes were washed twice with cold normal saline, fixed and stained with Leishman's stain. Colonies containing more than 50 cells were scored as reproductively intact, and the fraction of surviving cells (*S.F.*) after various drug or radiation treatments was calculated from the expression:

$$(1) \qquad S.F. = \frac{\text{control colonies}}{\text{experimental colonies} \times \text{dilution factor}}$$

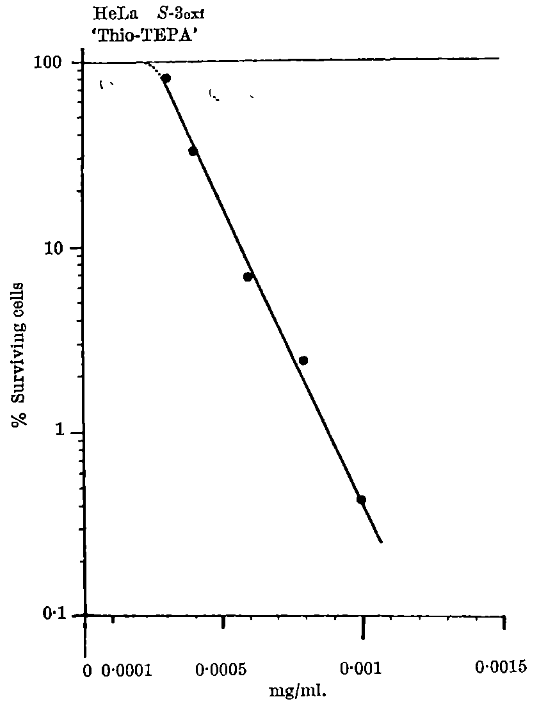

Fig. 3. Dose-response to 'Thio-TEPA', HeLa *S*-3oxf., fraction of surviving cells (log scale) versus dose in mg/ml. (linear scale)

The dose-response curves obtained in these experiments are shown in Figs. 1–6, where *S.F.* is plotted against the dose of the drug used. Each point represents the average of at least four independent determinations of surviving fraction and most points represent several thousand counted clones. Experiments in which control plating efficiency $\left(\frac{\text{No. of colonies reproductively intact}}{\text{No. of cells initially plated}}\right)$ was lower than 30 per cent were rejected, as it was felt that surviving clones from these experiments might represent an inadequate and potentially biased sample of the cell population.

Dustin[8] in 1947 coined the term 'radiomimetic', which has been widely used by many authors, uncritically accepted by many clinicians responsible for the care of cancer patients, and recently advanced again by Elson[9], to describe the action of chemotherapeutic agents which mimicked effects of total-body *X*-irradiation. The present results allow us to examine at the cellular level whether this term is justifiable in any but the most superficial evaluation.

The reproductive survival of mammalian cells of many types both *in vivo* and *in vitro* to X-irradiation has been shown to be of the type illustrated in Fig. 7 (for examples see Porter[6]). When the fraction of cells surviving (on a logarithmic scale) is plotted against dose of radiation (on a linear scale), there is a 'shoulder' region followed by what appears as a simple exponential (straight-line) response. When these same data are re-plotted with a 'logarithmic' dose-scale, the curve has a continuing downward inflexion, as also shown in Fig. 7. This type of dose-response is clearly seen in the present results with X-rays (Fig. 1). Both 'HN3' and 'Thio-TEPA' produce dose-response curves of this 'X-ray type', as did the nitrogen mustard 'HN2' in another cell strain in Levis's recent studies[7]. However, in these curves the 'shoulder' region is much sharper and more closely resembles a true threshold below which no effect of the drug on cell survival is seen and above which survival decreases exponentially with dose (Figs. 2 and 3). The dose-response to 'Epodyl' is of the same general type, but without evidence of a 'shoulder'; the curve falls as a simple exponential with depression of surviving fraction at even the smallest doses (Fig. 4). In investigations with ionizing radiation, the presence or absence of a 'shoulder' has been closely correlated with the ability or failure of cells to recover a certain amount of sub-lethal damage when doses are delivered as multiple fractions separated by intervals in time[10]. Whether this also applies to fractionated doses of chemotherapeutic agents is at present being investigated in this laboratory.

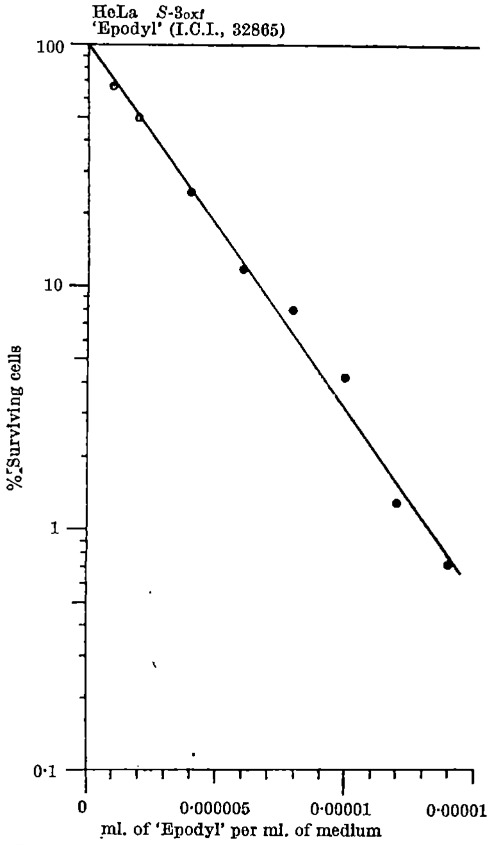

Fig. 4. Dose-response to 'Epodyl', HeLA S-3oxf., fraction of surviving cells (log scale) versus dose in ml. per ml. of growth medium (linear scale)

The dose-response to mannitol mustard ('Degranol') in both cell types is shown in Fig. 5. In both HeLa and the strain *L* fibroblast, the dose-response curve describes a straight line when dose on a logarithmic scale is plotted against percentage survival (log). This is typical of the response to many drugs[11], and its theoretical form is called the 'poison' type of curve in Fig. 8. Thus, with 'Degranol', the same percentage increment in dosage produces the same (log) decrease in survival, whereas with radiation, 'Thio-TEPA' and 'HN3' the same absolute increment in dose produces the same (log) decrease in survival. Clearly, at a cellular level, 'Degranol' is not radiomimetic, although its biologically active moiety is presumably the same as that of the 'radiomimetic' nitrogen mustard 'HN3'. This difference may have clinical significance, for an agent which produces an 'X-ray' type dose-response will be far more liable to catastrophic over-dosage than an agent showing the 'Degranol'-type response where the same percentage error in dose will produce the same percentage change in survival regardless of the absolute dose given, large or small.

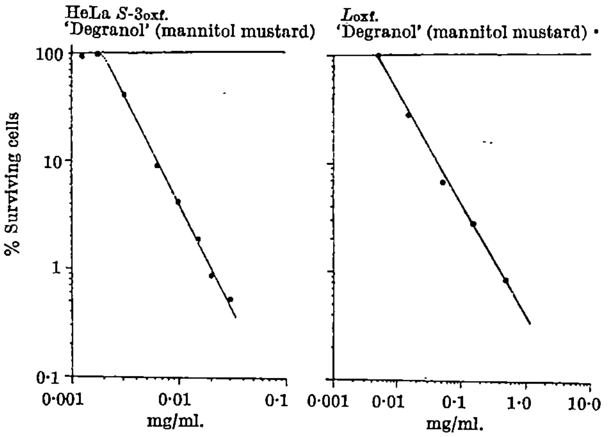

Fig. 5. Dose-response to mannitol nitrogen mustard ('Degranol'). Note that fraction of surviving cells (log scale) is plotted versus dose in mg/ml. on a logarithmic scale

The dose-response to the thymine analogue 5-fluorouracil (Fig. 6) is of different interest. Although the continuous presence of this agent produces a catastrophic dose-response curve with minute increments in dose producing vast decreases in cell survival once a threshold dose is exceeded, the dose-response to 24-h exposure to the drug starts similarly steeply above a threshold but

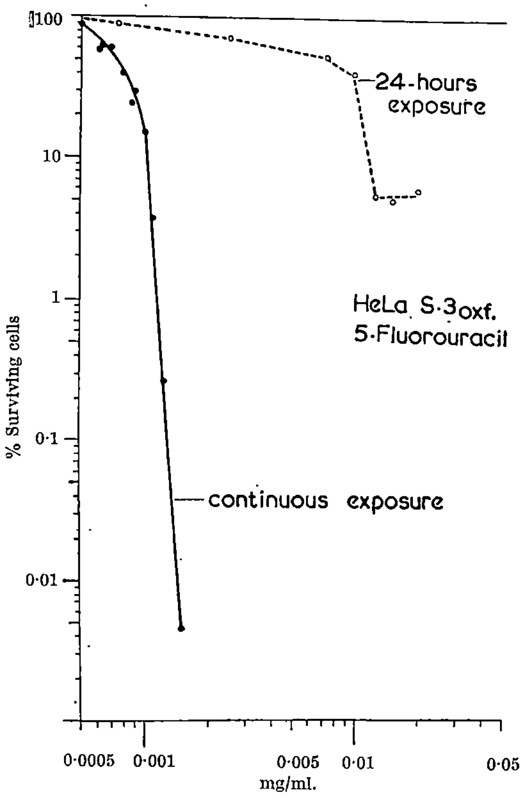

Fig. 6. Dose-response to 5-fluorouracil, HeLa S-3oxf., fraction of surviving cells (log scale) versus dose in mg/ml. on a logarithmic scale. Note that for 24 h exposure to the drug, the percentage of surviving cells is never decreased below 6 per cent (see text for discussion)

New Biochemical Separations

A. T. JAMES, Unilever Research Laboratory, Sharnbrook, Bedford, and
L. J. MORRIS, Unilever Research Fellow, Brunel College of Technology, London

This reference and laboratory handbook for chemists, biochemists, clinical analysts and medical research workers presents the most up-to-date account (with extensive bibliography to 1963) of new and important methods for the separation of biochemical compounds. All contributors are acknowledged authorities who have themselves developed the methods they describe.

The editors have avoided lengthy treatment of older methods, and have concentrated on full descriptions of the newest and most promising techniques. They have included detailed experimental data of applications to biochemical problems. The emphasis is on practical details for laboratory use, including modern refinements of technique which are not always made clear in research communications.

Biochemistry and Behavior

S. EIDUSON, Neuropsychiatric Institutes, University of California, Los Angeles,
E. GELLER and A. YUWILER, Veterans Admin. Centre and Univ. of California, Los Angeles, and
B. T. EIDUSON, Reiss-Davis Clinic for Child Guidance, Los Angeles

This book deals with the chemical substances that affect the human mind—both those which cause disturbances and are used in studying abnormal conditions, and all the tranquillizers and other drugs which relieve mental disease.

The authors have made over 2,000 pertinent studies of humans and animals from both biochemical and behavioural sources, and have submitted them to analysis and evaluation. Thus they have examined behavioural studies involving biochemical factors, and related the latter to the larger framework of biochemical concepts; similarly they have tried the same methods with biochemical studies having behavioural factors, relating the latter to the more general categories of behaviour.

Smoking and Health

This is the complete report of the Advisory Committee to the Surgeon General of the United States Public Health Service, which has been so much discussed recently in the press, on radio and television.

SMOKING AND HEALTH contains full scientific results of the scientific investigation of this human dilemma. Many people, who are dissatisfied or unconvinced by the shortened extracts which have been published, will wish to study the full text of the report for themselves.

Buyers will include public and specialist libraries, workers in the fields of medicine, psychology, biochemistry and sociology; the tobacco and the other industries, and educational authorities.

"The book is well produced; there are very few misprints and the tables and diagrams are excellent." *Nature*.

387 *pages* (*London bound edn. in cloth boards*), 27*s.* 6*d. net*

Biochemical Engineering

F. C. WEBB, Guinness Lecturer in Biochemical Engineering, University College, London

"Why has a marriage of biology and engineering become inevitable ? The table of contents of Dr. Webb's book gives the answer. Although some of the topics are far from new, others, such as antibiotics, are not only comparative newcomers, but may be said to have forced this getting together of biochemistry and engineering. Biochemists and microbiologists should be thankful for the union; they are now so much concerned with working under sterile conditions with pure cultures in large-scale industrial operations." *Nature*.

Inhaltsübersicht:

"Friedrich Dessauer zum Gedächtnis." Von B. Rajewsky

Erster Teil: Einleitung.—Biologische Quantenphysik. Formalismus der quantenbiologischen Depot-(=Treffer) Theorie. Quantenbiologie in der Genetik. Neuere Ergebnisse und Probleme. Anhang.

Zweiter Teil: Der heutige Stand der Quantenbiologie. Von K. Sommermeyer. Grundlagen: Allgemeine Treffertheorie. Energieleitung in festen Substanzen und innerhalb von Makromolekülen. Das aktive Wasser.—Anwendung der Treffertheorie in der allgemeinen Strahlenbiologie: Direkte Strahlenwirkung auf Enzyme, Viren und Phagen, vorwiegend auf trockene Enzyme, Viren und Phagen in vitro. Inaktivierung von Enzymen in vivo. Inaktivierung von E. Coli. Inaktivierung der Hefezellen. Chromosomen-Abberrationen. Mutationen, insbesondere Genmutationen (Punktmutationen). EPR-Spektren in bestrahlten biologischen Objekten.—Spezielle biologische Reaktionen durch sichtbares Licht: Statistik der Elementarreaktionen im Auge beim Sehen. Physik der Photosynthese.—Namenverzeichnis.

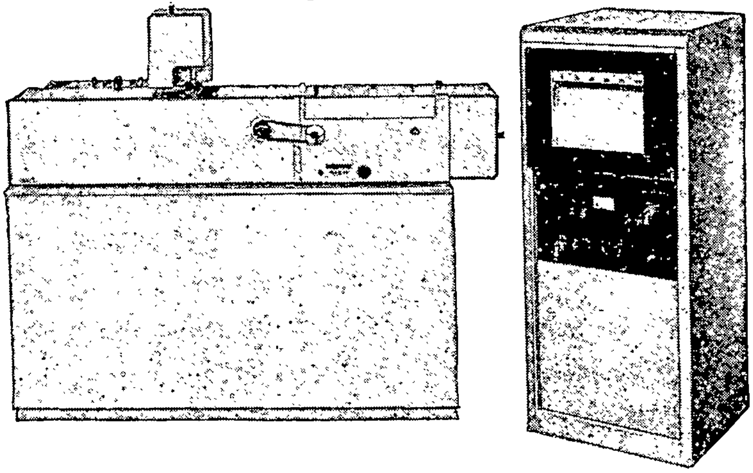
FOR HIGH PERFORMANCE

in routine analysis and research



CF4DR CF4NI

HIGH PERFORMANCE DOUBLE-BEAM RECORDING SPECTROPHOTOMETERS

Noted for photometric accuracy, these OPTICA spectrophotometers include *as standard* a number of features which distinguish them as outstanding among high-performance instruments.

CF4DR Range 185-750 mμ
Price £2,600

CF4N1 Range 185-3,200 mμ
Price £2,800

These instruments are manufactured completely at our Works and are installed free of charge.

Full details of the CF4DR and CF4N1 and other OPTICA spectrophotometers will be forwarded on request.

Standard Features Include:

* Grating Monochromator.
* Linear Transmittance and Absorbance Recording.
* High Resolution.
* Photomultiplier Detector.
* Single Beam Recording.
* Five Scale Expansion Ranges 0-10%T, 0-100%T, 75-125%T, 0-1A, 1-2A.

Complete range of attachments available.

Service Centres at London, LARkswood 2603; Manchester, CENtral 0937 and Newcastle, Low Fell 75002

e of possibilities with this,

LLETT & SIBERT

Q Which routine fluorescence microscope with binocular costs less than £300?

A The Gillett & Sibert Conference.

Q Which microscope offers you the facilities of brightfield, darkground, phase contrast (positive or negative) *and* fluorescence for less than £500—with photo-micrographic attachments and coupled ultra sensitive light meter included within that price?

A The Gillett & Sibert Conference.

Q Which microscope allows you to make colour photographic exposures of your fluorescent specimens in two—three minutes without bleaching?

A The Gillett & Sibert Conference.

Q Is there a microscope available which is one neat, compact and portable unit, with built-in light source *and* built-in transformer?

A Yes—the Gillett & Sibert Conference.

Q What do you need to adapt a standard research-type Conference microscope for fluorescence?

A A set of filters.

Q Which is the safest and simplest microscope to set up and use for fluorescence observations and photo-micrography?

A The Gillett & Sibert Conference.

Q Are you yet convinced?

A No—of course you're not, for only seeing is believing.

Q May we have the chance to show you this equipment, and convince you of what we say?

Why not contact us for further information, and at the same time, tell us which fluorochromes you are using?

Where reliability is paramount ...men count on Electrothermal quality

In laboratories, above all, men can only be as effective as their equipment allows. With Electrothermal heating equipment and scientific instruments, the scientist can get on with the job in the certain knowledge that his equipment is the finest available and has been subjected to the closest possible scrutiny before leaving our factory. For it is our belief that highly skilled men are entitled to be released from the delay, frustration and inaccuracies which faulty, inefficient equipment brings.

Available from laboratory supply houses. For catalogue and leaflets, please write or phone **Electrothermal Engineering Ltd., London, E.7. GRA 9911. TELEX: 24176**

Berkeley Square House, London, W.1

POLYCYCLIC HYDROCARBONS

By **E. Clar**

Published jointly by Academic Press and Springer-Verlag, Germany

- presents complete and up-to-date information of value to chemists and physicists and to technologists in dye, coal, and oil industries
- deals with nomenclature, general background data and theories regarding spectra and magnetic and electrical properties, and interrelations between different types of polycyclic systems
- gives a survey of general methods, describes linearly annelated hydrocarbons, other *kata*-annelated, *peri*-condensed, those in which one or more polycyclic CH_2 groups are present and those with formally fixed double bonds.

Volume 1, 1964, 488 pp., 126s.
Volume 2, 1964, 488 pp., 140s.

NUMERICAL METHODS OF REACTOR ANALYSIS

By **Melville Clark**, Jr. and **Kent F. Hansen**

- introduces topics of numerical analysis frequently used in the nuclear reactor field
- provides methods by which machine calculations are performed on practical problems in the reactor field, with emphasis on those methods specific to the field
- gives the rudiments of matrix algebra, difference equations, and the methods of solving these equations

October 1964, about 350 pp., 84s.

SPECTRA-STRUCTURE CORRELATION

By **John P. Phillips**

- collects in this volume, prominent generalization, rules and summaries, both graphical and tabular, of spectra of organic functional groups and compound types
- compares the empirical relationships of structure and spectra in all regions from far ultraviolet to far infrared
- guide to the most suitable regions of the spectrum for experimental characterization, and a synopsis and abstract of the secondary as well as primary literature

1964, 172 pp., 48s.

BRIDGED AROMATIC COMPOUNDS

By **B. H. Smith**

- covers the chemistry of all bridged aromatic systems. Since the study of bridged non-benzenoid aromatics is growing rapidly, particularly in the ferrocene area, this encyclopedia of cyclophane chemistry will be a primer for bridged ferrocenes and other similar compounds
- explains the chemical 'and physical behavior of many of the bridged aromatics through reference to the physical methods of analysis, infrared and ultraviolet spectroscopy, nuclear magnetic and electron paramagnetic resonance, and X-ray diffraction

November 1964, about 525 pp., 100s.

CARBENE CHEMISTRY

By **Wolfgang Kirmse**

- comprehensive and critical account of current knowledge
- exhaustive survey of carbene formation and carbene reactions, supplemented by chapters on underlying theoretical topics—excess energy effects ; spin states
- evaluates present status and stimulates further research

September 1964, 302 pp., 76s.

REFRACTORY TRANSITION METAL COMPOUNDS

HIGH TEMPERATURE CERMETS

Edited by **G. V. Samsanov**

Translated by **Scripta Technica, Inc.**

Translation edited by **G. E. Gurr** and **D. J. Parker**

- covers studies of refractory compounds of transition metals carried out by both direct and indirect methods
- acquaints the technical reader with the state of the art in the analysis of properties of refractory compounds, as well as with the principles of classification of such compounds and the methods for their systematic investigation
- also includes a number of metallographic and engineering investigations

October 1964, 221 pp., 72s.

CHEMICAL TRANSPORT REACTIONS

By **Harald Schäfer**

Translated from the German by **Hans Frankfort**

- extensive survey of the literature covering such aspects as experimental and theoretical principles, the transport of solid substances and its special applications, information of the reaction process in the gas phase, chemical transport processes as an aid in preparative chemistry, and the use of transport experiments in the determination of thermodynamic values

September 1964, 221 pp., 54s.

THE CHEMISTRY OF CEMENTS

Edited by **H. F. W. Taylor**

- describes the chemistry of calcium silicates and aluminates, both anhydrous and hydrated, and related compounds
- deals with the more important chemical aspects of the manufacture and use of cements
- considers all the main cements used in building including Portland, aluminous, slag, expansive cements, pozzolanas, and calcium silicate products

Volume 1, 1964, 460 pp., 100s.
Volume 2, 1964, 442 pp., 95s.

Detailed information available upon request

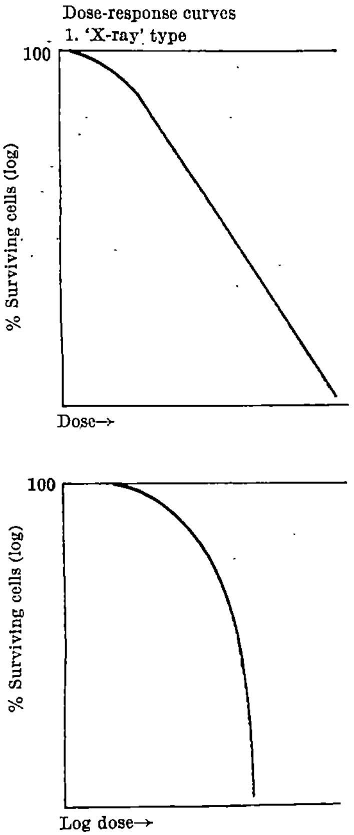

Fig. 7

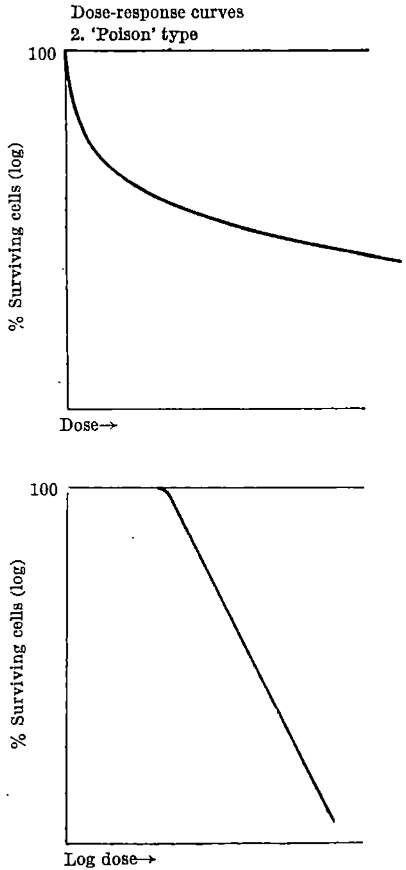

Fig. 8

reaches a point at which the percentage of surviving cells does not change in the face of increased concentrations of the drug. This becomes understandable when it is realized that in the HeLa *S*-3_{oxf}. line, with its average doubling time of 40 h, a certain proportion of cells do not enter DNA synthesis within any 24-h period. If tritiated thymidine is added to the growth medium for 24 h, the cells then fixed, and stained autoradiographic preparations made, it is seen that approximately 6 per cent of the cells fail to take up the radioactive DNA precursor and remain unlabelled[12]. It is this group of cells which survive a 24-h exposure to 5-FU because they are never called on to make DNA in the presence of the analogue, and no reasonable increase in the drug dose when administered for only this 24-h period can be expected to alter the approximate 6 per cent survival (Fig. 6). This type of observation at a cellular level may have great relevance to the schedules by which anti-tumour agents are administered to the cancer patient.

I thank the Damon Runyon Memorial Fund for their continued support of the cell culture laboratory, and Dr. F. Ellis, director, Radiotherapy Department, and Mr. R. Oliver, principal physicist, for helpful discussion. Misses M. A. Luschen, M. Jackson and J. Restall gave invaluable technical assistance. 'Trillekamin' ('HN3') was supplied by the courtesy of Crookes Laboratories, Ltd., and 5-fluorouracil by the courtesy of Roche Products, Ltd. The Regional Blood Transfusion Centre, Churchill Hospital, Oxford, kindly provided the freshly drawn human serum used in these experiments.

REGULATION OF BACTERIAL ENZYME SYNTHESIS BY INDUCTION AND REPRESSION

By PATRICIA H. CLARKE and W. J. BRAMMAR
Department of Biochemistry, University College, London

ENZYME synthesis in bacteria can be induced or repressed by changes in the external environment. The essential similarity of these two processes was explicitly recognized by Jacob and Monod[1] when they put forward the repressor-operator model for the regulation of enzyme synthesis. In general, enzyme repression has been associated with biosynthetic systems and enzyme induction with degradative enzyme systems. The common feature of these two types of regulation is thought to be the possession of one or more regulator genes, responsible for producing a regulator molecule termed the cytoplasmic repressor. In a typical repressible system the cytoplasmic repressor is assumed to be incomplete, and active in repressing enzyme synthesis only when combined with the low

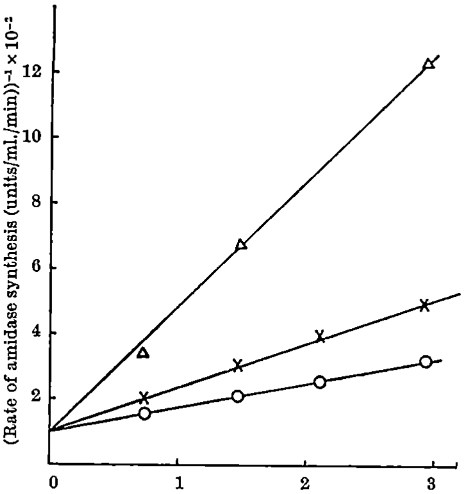

Fig. 1. Effect of cyanoacetamide on the rate of amidase induction by *N*-acetylacetamide. *Pseudomonas aeruginosa* 8602/A was grown overnight at 37° on a mechanical shaker in minimal salt medium with 0·01 M succinate (growth limiting concentration). 2-ml. samples were incubated with appropriate concentrations of *N*-acetylacetamide and cyanoacetamide. (Total volume, 2·5 ml.) 0·25 ml. samples were removed after 10 and 40 min for enzyme assay by the hydroxamate method (ref. 6). △, $1{\cdot}4\times10^{-4}$ M cyanoacetamide; ×, $3{\cdot}4\times10^{-5}$ M cyanoacetamide; ○, No cyanoacetamide

molecular weight co-repressor molecule. In a typical inducible system the cytoplasmic repressor is considered to be fully effective, and able to prevent enzyme synthesis, until it is rendered inactive by combination with the inducer molecule. Inducible enzymes are also subject to regulation by other cell metabolites and since many, though not all, enzymes are repressed by glucose, this was known for a long time as the glucose effect. Magasanik[2] considered that repression by glucose and other carbon compounds was a specific effect due to particular cell metabolites, and suggested the term 'catabolite repression'. McFall and Mandelstam[3] showed that glucose repression of β-galactosidase, serine deaminase and tryptophanase in *Escherichia coli* is due not to glucose directly, but to metabolites of glucose which are also intermediates in the degradative pathway of the substrate inducers of these enzymes. These findings suggest that catabolite repression is not a general property of cell metabolites but can be as specific as end-product repression or enzyme induction. McFall and Mandelstam[3] concluded that catabolite repression operated at a site other than the cytoplasmic repressor. Among the evidence for this view were the findings that strains of *E. coli* which were either i^- or 0^c constitutive for β-galactosidase were still subject to catabolite repression, and that increased inducer concentration did not reverse catabolite repression[3,4].

We have some evidence from studies with *Pseudomonas aeruginosa* to show that catabolite repression can be affected by changes in the inducer concentration. *P. aeruginosa* produces an amidase which hydrolyses a number of aliphatic amides and also transfers the acyl moiety to hydroxylamine to form the corresponding hydroxamate[5,6]. The enzyme can be induced by adding acetamide, one of its substrates, to exponentially growing cultures. A few amides, including *N*-acetylacetamide, are inducers but not substrates. Other substituted amides including cyanoacetamide prevent enzyme induction by both substrate and non-substrate inducers. We have shown that in exponentially growing cells this effect of cyanoacetamide can be reversed by increasing the concentration of either acetamide or *N*-acetylacetamide[6]. The relative concentrations of these amides giving enzyme induction or repression under these conditions suggested that they all acted at the same site in the cell and that the affinities for binding at this site were in the order acetamide > cyanoacetamide > *N*-acetylacetamide. The amidase is also subject to catabolite repression, and we examined the effect of increasing the inducer concentration under conditions similar to those used for the experiments on amide analogue repression. We were able to show that with acetamide as inducer, catabolite repression by propionate could be partially relieved by increasing the concentration of acetamide. There are serious disadvantages in attempting to examine this phenomenon in exponentially growing cells. The concentration of carbon compounds required in the medium to give a rapid growth rate is such that there is likely to be a high concentration of metabolities in the cells, and in particular, the conditions are favourable for producing a high concentration of catabolite repressor molecules. We have therefore re-examined amide analogue and catabolite repression with cells the growth of which has been limited by the supply of carbon compounds in order to deplete the cell carbon pool.

Amidase synthesis is induced by acetamide or *N*-acetylacetamide in carbon-starved cells with little or no lag and continues for at least 1 h. Fig. 1 shows the results of experiments to determine the effect of cyanoacetamide on the rate of induction by *N*-acetylacetamide under these conditions. The induction rates were measured for *N*-acetylacetamide alone, and at two different concentrations of cyanoacetamide. The reciprocal of the rate of enzyme synthesis is plotted against the reciprocal of the inducer concentration. The graph obtained is similar to a Lineweaver–Burke plot for competitive inhibition of enzyme activity by substrate analogues. These results support the conclusions drawn from the experiments with exponentially growing cells that amide analogues compete at the same site in the cell. From the data of Fig. 1 a K_{Inducer} (the concentration of inducer giving half-saturation of the induction system) was calculated. For *N*-acetylacetamide the K_{Inducer} was approximately 10^{-3} M. In the same way, the 'inhibitor constant' for cyanoacetamide repression was calculated to be approximately 5×10^{-5} M.

Fig. 2 gives the results of a similar experiment in which *N*-acetylacetamide is used as the inducer and succinate as the catabolite repressor. The graph shows that succinate repression is also dependent on inducer concentration, but the relationship in this case is not that of a simple competitive inhibition. It seems reasonable to conclude that repression by succinate is different in character from that produced by cyanoacetamide. We have not yet determined whether there is a single specific catabolite repressor for this system. Propionate was also examined under these conditions and gave results similar to those obtained with succinate.

One possible site of action of both amide analogue and catabolite repressors is at the point of entry of amides into

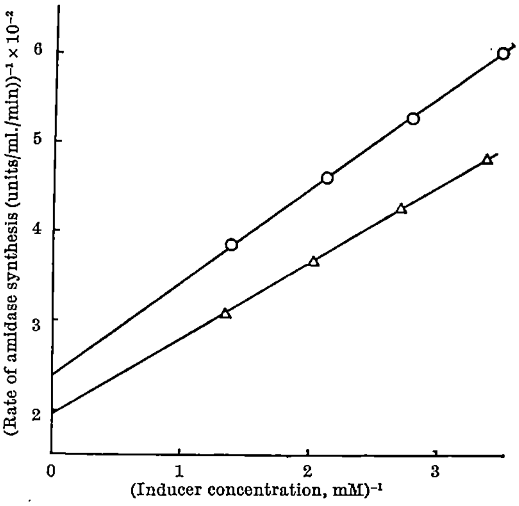

Fig. 2. Effect of succinate on the rate of amidase induction by *N*-acetylacetamide. Experimental conditions as for Fig. 1 with succinate replacing cyanoacetamide. ○, 10^{-2} M succinate; △, No succinate

the cell. This possibility was examined by measuring the uptake of *N*-acetylacetamide labelled with carbon-14 by exponentially growing cells under conditions allowing enzyme induction in the absence of added repressors. Cyanoacetamide at a concentration of 10^{-2} M completely repressed amidase induction by 5×10^{-3} M N-acetylacetamide and had no effect on the uptake of labelled *N*-acetylacetamide. Amidase induction by 10^{-3} M *N*-acetylacetamide was almost entirely repressed by 10^{-2} M succinate. There was no significant effect on uptake of labelled *N*-acetylacetamide. It seems clear that neither cyanoacetamide nor succinate represses the synthesis of this enzyme by preventing the entry of inducers into the cell.

The inducer of an enzyme is thought to react with the cytoplasmic repressor molecule and thereby release the structural genes from repression. For theoretical reasons the cytoplasmic repressor is likely to be a protein and there is some experimental support for this view[7]. The specificity of the cytoplasmic repressor for its inducer would be expected to be similar to the specificity of an enzyme for its substrate. In these terms we have no difficulty in accounting for cyanoacetamide repression of enzyme induction, by both substrate and non-substrate inducers, as direct competition for the inducer site of the cytoplasmic repressor. The site of action of catabolite repression is more difficult to identify, but it could also be the cytoplasmic repressor. One possible interpretation of the kinetic results given in Fig. 2 would be that succinate represses induction by reacting with the cytoplasmic repressor at a site other than the inducer binding site. This would be essentially the same phenomenon as the allosteric interactions between an enzyme and its substrate and feed-back inhibitors[8]. Catabolite repressors would then be expected to combine with the cytoplasmic repressor in such a way that its repressing activity was increased, and the inducer to combine with it in such a way that its repressing activity was decreased. This could happen if combination of the cytoplasmic repressor with the catabolite repressor increased its affinity for the operator and combination with the inducer decreased it. On this basis the mechanisms of action of the cytoplasmic repressors of inducible and repressible enzymes become almost identical. Catabolite repression is widespread among inducible enzymes but in a few cases only has the possibility of reversal by increased inducer concentration been examined[3,4,9]. If conditions had been used in which the concentration of compounds in the metabolic pool had been severely reduced it might have been possible to show some effect of inducer concentration on catabolic repression. In this connexion it is perhaps significant that the concentration of isopropyl-β-D-thiogalactoside required for the maximum rate of induction of β-galactosidase is $1{\cdot}4 \times 10^{-3}$ M in glucose medium and only 5×10^{-4} M when glycerol is used as the carbon source[10]. The antithesis of catabolite repression of inducible enzymes would be metabolite induction of repressible enzymes. An example of this is ornithine transcarbamylase which is repressed by arginine and induced by glutamic acid[11].

The first recognizable event in enzyme induction is the production of a specific messenger RNA, and this has been demonstrated by isolating enzyme specific DNA RNA hybrids from several inducible enzyme systems[12]. Nakada and Magasanik[13] have shown that induction of β-galactosidase and catabolite repression by glucose operate at the stage of synthesis of the specific messenger RNA. However, Loomis and Magasanik[10] rejected the hypothesis of allosteric interactions of inducer and catabolite repressor with the cytoplasmic repressor. They examined catabolite repression by glucose under conditions in which it was reasonable to suppose that the cells did not contain any *i* gene product. Since $i^-_{\text{del}}\ z^+$ mutants were not available they used mutants with a complete Lac region deletion, which were $i^-z^-y^-$, as F^- recipients, and examined the effect of glucose on the constitutive phase of β-galactosidase synthesis which occurs during the first hour after gene transfer[14]. There was marked repression by glucose, but it is by no means certain that *i* gene products were absent. The period of constitutive enzyme synthesis after i^+z^+ transfer represents a very complex situation. The simple explanation is that the *z* gene can express itself immediately but the *i* gene can only do so after some time. Loomis and Magasanik[10] point out that the *i* gene product is probably also made immediately, and the constitutive enzyme synthesis covers the time required for the cytoplasmic repressor to reach an effective concentration. If this were the case, then during the early stages, when the concentration of the cytoplasmic repressor was very low, any factor which increased its repressing activity, such as combination with a catabolite repressor molecule, would repress enzyme synthesis. We suggest that to resolve the problem of catabolic repression far more quantitative data are required on the interactions of inducers and catabolite repressors.

EVOKED RESPONSES TO NUMERICAL AND NON-NUMERICAL VISUAL STIMULI WHILE PROBLEM SOLVING

By DR. ROBERT M. CHAPMAN and HENRY R. BRAGDON

Institute for Behavioral Research and Walter Reed Army
Institute of Research, Washington, D.C.

EXPERIMENTS attempting to deal with the relation between evoked responses and 'meaningfulness' may be classified into the following categories: (1) distraction procedures where evoked responses to test stimuli are compared with and without 'distraction stimuli'[1]; (2) attention procedures where the subject is instructed to attend to some stimuli and not to others[2]; (3) habituation and learning procedures[3]. Experiments using these procedures have shared three common difficulties: (1) assurance of the 'meaningfulness' of the stimuli to the subject, (2) separation of effects due to general states of the organism, such as activation-level, (3) adequate controls for the physical stimulus reaching the receptors[4].

The present experiment introduces a new procedure. Subjects were instructed to solve simple problems that required the perception of numerical visual stimuli presented

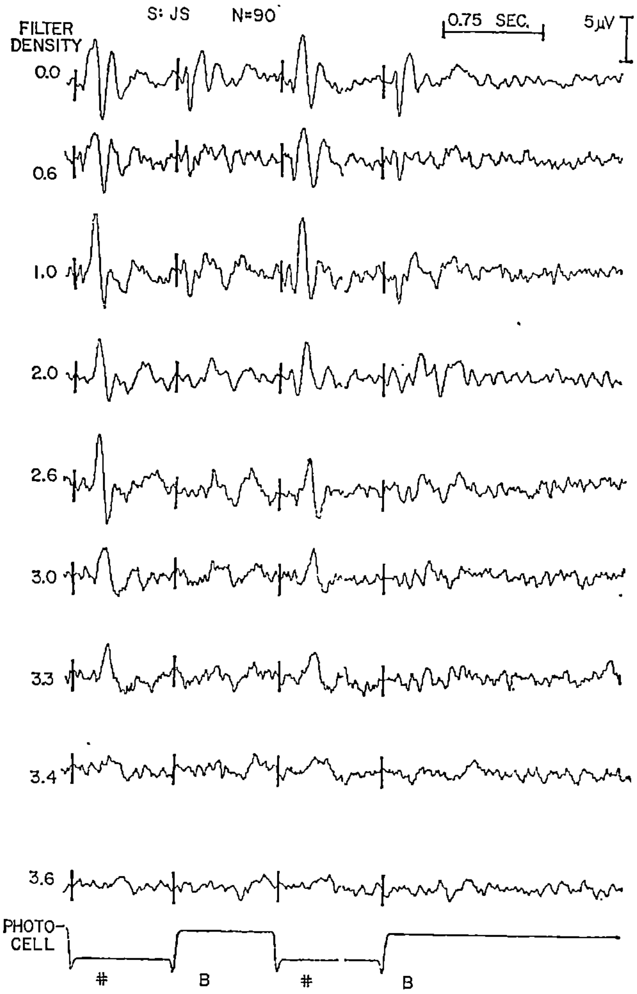

Fig. 1. Evoked responses to numerical (# = number) and non-numerical (*B* = blank) visual stimuli of various luminances while the subject is using the numbers. Positive at the central-parietal electrode is up in the evoked response. The photocell average shows the relative energy of the number and blank stimuli. Relative luminance of runs indicated by neutral filter density; blank at 0·0 filter density was 7·6 ft. lamberts

in sequence. Other visual stimuli, irrelevant to solving the problems, were a regular part of the stimulus sequence. Electrical responses evoked by these stimuli and the subjects' performance were recorded. Differences in evoked responses were found that may not be attributed to the physical energy of the stimuli but are related to their meaningfulness in the sense of their task relevance.

The stimuli consisted of white luminous figures presented every 3/4 sec in sequence, for example, number, blank, number, blank. Bina-View decoder display units (Industrial Electronic Engineers, Inc.) were automatically controlled by a paper tape reader driven by a synchronous motor through a gear train. Sync pulses also were derived from the punched tape. The subject viewed two adjacent windows (36 × 33 mm) at a distance of 160 cm. In the left window appeared the stimulus sequence. In the right window, covered by a green filter, appeared the answer stimuli. The blank occurred when no figure mask interposed between the stimulus light and the window of the display unit and appeared as a bright, blank field. During the time when a number or plus was not being presented, the blank was maintained at both windows. For some of the data (for example, Fig. 2) a different light source made the problem stimuli approximately 1 log unit more intense. The maximum luminance of the blank stimulus was 76·4 ft. lamberts measured by a MacBeth illuminometer. The subject's room was dimly illuminated (< 0·01 ft. lamberts). The luminance was controlled by Wratten neutral density filters placed in front of both windows (for example, Fig. 1). The subject's task was to say which of the two numbers was numerically smaller, 'first' or 'second', or whether they were 'even'. Then the correct answer was presented as a green luminous figure. This sequence constituted a trial lasting 7·5 sec. Each stimulus was a brief darkening (0·04 sec) followed by the new figure which was maintained until the next stimulus occurred (Fig. 1, photocell trace). Ninety trials constituted an uninterrupted run (11¼ min). During each run the numbers (0–9) were randomized and the sequence of numerical and non-numerical stimuli was constant.

The evoked responses were obtained by bipolar recording from EEG silver disk electrodes fixed to the scalp on the midline 2·5 cm below the vertex and 2·5 cm above the inion[5] with the ground electrode attached over the mastoid. Eye movements were monitored by electrodes placed in the external canthis and below one eye. Other kinds of activity were recorded on additional channels at various times. After suitable amplification the evoked responses were revealed by computer averaging of the activity during 90 trials. The electrical activity was amplified by a Grass Model 6 EEG machine and recorded on *FM* magnetic tape. The computer system was designed by W. Kropfl. The sampling rate was 8 msec/sample for each channel. The computer (Packard-Bell 250) was programmed to average 1536 samples over the 90 trials and to graph the average waveforms on an X–Y plotter. The low frequencies were limited only by the EEG machine which was set to be 20 per cent down at 5 c/s. High-frequency muscle activity was scarcely ever obtained from the evoked response sites.

Representative evoked responses from one of the subjects are shown in Fig. 1. Each of the stimuli in the trial sequence evoked an average response. The evoked responses were consistently different to the number and to the blank stimuli. Although the physical intensity of the blanks was approximately 4 times greater, the responses to the numbers were larger. This effect held over a considerable range of luminances (2,000 to 1, Fig. 1).

With all neutral filters from 0·0 down to 3·3 this subject answered 100 per cent of the problems correctly. His accuracy dropped to 58 per cent correct at a density of 3·4 and 50 per cent at 3·6. This was the luminance region for threshold of number recognition. Appropriately this was the luminance region where the evoked responses abruptly reduced in amplitude. In the luminance range where the subject performed with 100 per cent accuracy (0·0–3·3), the size and waveform of the evoked responses were controlled to some extent by the light luminance. Generally as the luminance was decreased the amplitude decreased, latency increased and the waveform simplified. However, the amplitude of the responses to the number stimuli did not decrease appreciably until the recognition threshold was reached. In marked contrast, the amplitude of the responses to the blank stimuli decreased rapidly with lowered luminance. From this comparison it appears that the amplitude of the evoked response is only weakly controlled by the physical luminance of the visual stimulus. The waveforms of the responses to number and blank stimuli are different and the differences may not be attributed to the stimulus luminance. Data from monopolar recording show that the larger components of these evoked responses come from the central-parietal site rather than the occipital site.

The main finding appears to be general. Larger evoked responses were obtained to number stimuli than to blank stimuli in all persons tested (3, Fig. 2; another, Fig. 1).

A variety of control runs have been made, some of which are illustrated in Fig. 2. The effect of a different irrelevant stimulus and different sequences of stimuli are illustrated in the top 3 lines. A plus sign (+) was used because it was similar to the number stimuli in having approximately the same luminance and general meaning by virtue of the subject's language history. When a plus

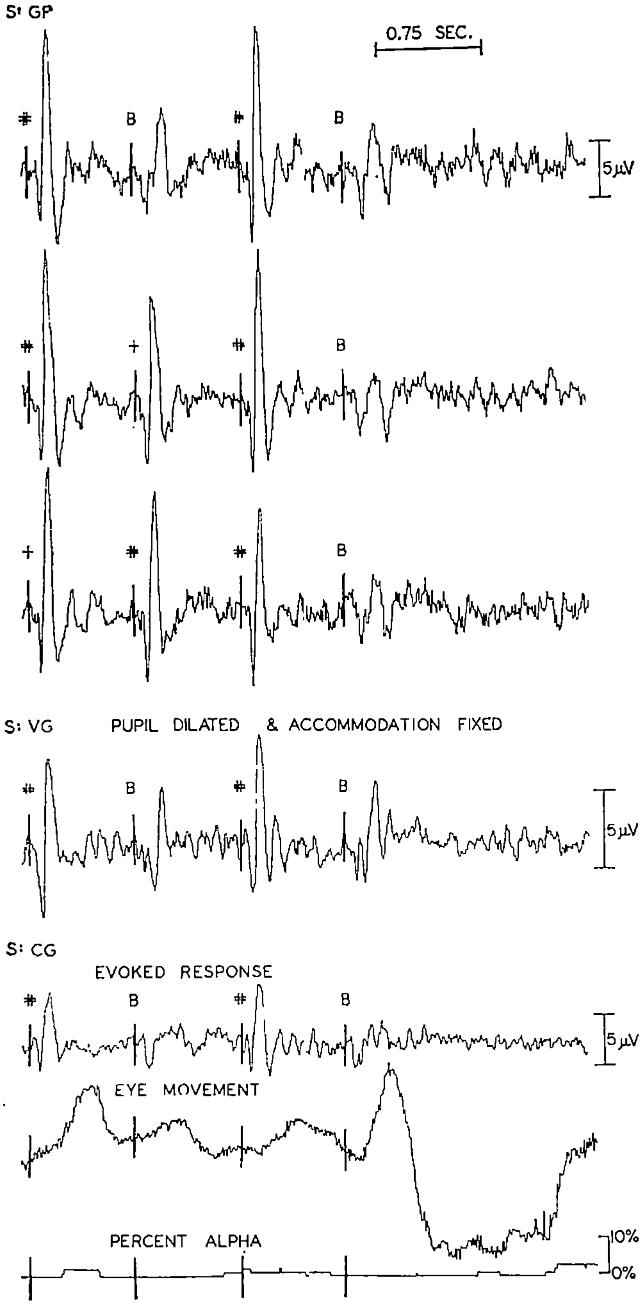

Fig. 2. Evoked responses from three subjects illustrating control runs. Blank luminance for *GF* and *VG* was 76 ft. lamberts; for *CG*, 7·6 ft. lamberts

was used in the second position in place of a blank (line 2), the response tended to be larger and have a waveform more like the number response. Nevertheless, the response to the irrelevant plus was smaller than the response to the relevant number. When a plus was used in the first position (line 3), its response was larger. It is suggested that its task relevance is increased in this position in that it signifies the start of each trial.

The differences in evoked responses may not be attributed to changes in pupil size or accommodation, since the middle section of Fig. 2 was recorded with a cyclopegic drug. These monocular data also show that binocular viewing is not necessary.

The differences in evoked responses may not be attributed to eye movements, which were monitored by averaging the electro-oculogram. Eye movements occurred but were not consistently correlated with the size or waveform of the evoked responses (compare evoked response and eye movement lines at the bottom of Fig. 2). Eye movements were reduced during the stimulus sequence by training the subjects to fixate the centre of the window and to delay their verbal answer after the end of the stimulus sequence.

The differences in evoked responses may not be attributed to activation-level as indicated by amount of alpha rhythm in the EEG. The electrical activity which was averaged to obtain evoked responses was also delivered to an electronic scorer of alpha rhythm[6]. Each alpha burst above 15 μV was indicated by a voltage step which was averaged to indicate the course of alpha activity across the trial. Fig. 2 shows a case where the alpha activity was more frequent during the number stimuli than during the blank stimuli. Other subjects have shown the opposite time pattern of alpha activity and still others have had negligible alpha activity. Thus, the pattern of alpha activity varied considerably whereas the differences between evoked responses to number and blank stimuli were quite consistent. The experimental design also makes it unlikely that the evoked response differences are due to changes in general activation-level, since the relevant and irrelevant stimuli change every 3/4 sec within each stimulus sequence.

During some control runs the electroretinogram (ERG) was recorded with a contact lens electrode[7]. In contrast to the evoked responses, the ERGs were not smaller to the bright blank than to the number stimuli. These data indicate that the differences in central-evoked responses between number and blank stimuli are not due to peripheral mechanisms.

These findings may be explained by a variety of hypotheses.

Several features of this experiment bear emphasizing. Control stimuli (blank and plus) were used in every averaging run by making them a regular part of each stimulus sequence. Since they occurred in temporal proximity with the number stimuli, they rule out the possible role of any longer term changes, they save experimental time, and they avoid the problem of what the subject should do during control runs. In this procedure, the subject is busy with the numbers and presumably does not have time for extraneous activity during the control stimuli. The subject is required to do something with the stimuli and his performance is readily scored. Obtaining evoked responses from visual form stimuli such as numbers leads to many interesting experiments dealing with cognitive processes, perception, learning, etc. The use of meaningful stimuli and subject performance might also be a useful technique to reduce variability in experiments purporting to deal with sensory processes.

PHYSICS

The Temperature Scale

THE proposal made by Prof. J. C. Georgian[1] is in my view unsatisfactory in so far as it involves not only a change of unit but a change in the definition of the quantity, temperature. Temperature is a macrophysical quantity and confusion arises if it be given a pseudo-microscopic redefinition.

It would, however, be possible and unobjectionable were there to be defined a new unit of temperature, say 'the Georgian' with the unit symbol Geo, such that the molar gas constant became 1 J/kmole Geo. This would achieve many of the aims of Prof. Georgian without involving a redefinition of the quantity.

One must, however, note that a system involving a new unit of temperature, say, the Boltzmann with a unit symbol Bol, such that the molar gas constant became 1 J/molecule Bol, might prove to be even more attractive.

In my view, however, a more radical reform should be made. It would be appropriate to make entropy a primary quantity and temperature a derived quantity. I would introduce a unit of entropy, say the carnot with a unit symbol Car, such that the molar gas constant became 1 Car/kmole. The unit of temperature would then be the J/Car.

This change would lead to relations between temperature and entropy which were symmetric relative to the relations between pressure and volume or force and distance. When considering pressure and volume it has long proved convenient to regard thermodynamic pressure as defined as minus the derivative of internal energy with respect to volume at constant entropy. According to my scheme, one would define (thermodynamic) temperature as the derivative of internal energy with respect to entropy at constant volume. This is indeed used in many presentations of thermodynamics, but the traditional scheme of units in which temperature is regarded as primary and entropy as derived militates against a clear understanding of this approach.

Whatever may eventually be done about changes in this field it cannot in my opinion be too strongly stressed that these macroscopic quantities should retain definitions which do not confuse them with related but non-identical microscopic quantities. It is from such a confusion that the controversy about certain electromagnetic quantities stemmed.

E. J. LE FEVRE

Queen Mary College (University of London),
Mile End Road, E.1.

[1] *Nature*, 201, 695 (1964).

I BELIEVE Mr. Le Fevre's objections are due to the long-term habits of considering temperature measured by a degree (centigrade, Celsius, Kelvin, Fahrenheit, Rankine, etc.); hence, he feels it is necessary that the temperature should have some type of unit name. There is, of course, nothing wrong with this since, for example, we call the unit of energy, newton-metre, a joule, and power a newton-metre/second or joule/second, a watt. I am only proposing that the temperature be called by what it actually represents, that is a joule/kilomole, in the same manner that pressure is a newton/square metre.

While I appreciate Mr. Le Fevre proposing calling the new unit in my temperature scale a Georgian, I think that, if he feels it necessary to name this new unit, I suggest calling it a degree Joule, as it most closely names the temperature dimension of joule/kilomole. I maintain, however, that the molar gas constant can be dispensed with, as the temperature unit in the ideal gas law is determined from the fundamental M.K.S. units.

I suspect Mr. Le Fevre is also objecting to the idea that temperature has the dimensions of L^2/T^2 and feels that temperature needs a separate dimension. The ideal gas law shows from a macroscopic or phenomenological point of view that temperature is a measure of energy and on a specific energy basis has the units of L^2/T^2. On the other hand, from the microscopic or kinetic theory of gases it is shown that:

$$\overline{c^2} = \frac{3\theta}{M} \qquad (1)$$

where $\overline{c^2}$ is the mean square velocity of the molecules; M is the molecular mass number (molecular weight) of the gas; θ is the absolute temperature.

Equation (1) indicates that the temperature is directly proportional to the mean square velocity of the molecules in an ideal gas. Consequently, either from the phenomenological or statistical theory of gases we find that temperature is indeed an energy unit with the dimensions of L^2/T^2.

Only by understanding clearly that temperature is a measure of energy do we see that entropy from its definition is nothing but a dimensionless quantity which, however, is of great convenience and utility in thermodynamics. In addition, the probability theory of entropy shows clearly that entropy is a dimensionless quantity. Entropy is given by the expression:

$$s = k \log_e W + s_0 \qquad (2)$$

where now Boltzmann's constant, k, equals $1\cdot6604 \times 10^{-27}$ kilomole in the M.K.S. system with $\bar{R} = 1\cdot0$, and W is the probability. Therefore, Mr. Le Fevre's idea of introducing entropy as a primary quantity is extremely objectionable as he is attempting to force an essentially dimensionless quantity into some type of unit.

I believe that the real confusion has arisen from the fact that temperature has not been clearly defined as the energy unit it is, with the consequent proliferation of large numbers of extraneous units. Finally, the original proposal was to place temperature in the M.K.S. system of units and, hence, relieve scientific and engineering calculations of the unnecessary burdens of conversion factors.

Stress Waves in a Liquid Column

EXPERIMENTS have been carried out in which stress waves are propagated upwards through a vertical liquid column. For this purpose the apparatus previously described by me[1] was used except that a piston of shorter length (3 cm) was used.

Briefly, the liquid under test was contained in a vertical steel cylindrical tube fitted with a steel piston at its lower end and the upper end open. A positive pressure wave was generated in the liquid by firing a lead bullet of 0·22-in. calibre so as to strike the lower end of the piston normally at its centre. When this pressure wave reached the upper free surface it was reflected as a wave of tension. The pressure changes in the liquid were recorded by means of a horizontal steel pressure bar inserted into a 'porthole' below the liquid surface.

Records using ordinary tap water showed that tensions of the order of 7 atm. could be generated in the liquid. It was then decided to introduce gas nuclei into the water in order to examine their effect on the wave propagation. This was first done by using fresh 'soda water' in the tube;

the results were the same as those using tap water, that is, a tension wave could be transmitted. Secondly, a number of experiments were performed by arranging for a steady stream of small nitrogen bubbles to rise in ordinary tap water past the inner end of the pressure bar. The rate of production of these bubbles could be varied from about one bubble per sec to a fast turbulent rate. With a slow rate of bubble production the results were like those for ordinary water. With a fast bubble rate, however, the records showed that no stress wave, either of compression or of tension, was propagated.

In another type of experiment the effects accompanying wave propagation across a plane interface between two liquids which do not mix were investigated. For this purpose water occupied the tube to a level of 5 cm above the pressure bar and about 50 cm^3 of lubricating oil were then added. In this way records of events in the water at 5 cm below the water–oil interface were obtained. One would expect the upward wave of compression to be transmitted across this interface, but the behaviour of the downward wave of tension is not as predictable. The results showed, however, that a tension wave was propagated downwards.

It is hoped that further experiments on these lines will shed more light on the 'cavitation threshold' of liquids, that is, on the maximum tension that can be built up before cavitation sets in.

GEOPHYSICS

Collision Frequency in the Ionosphere and Solar Activity

IN a recent publication, Belrose and Hewitt[1] have produced evidence for a variation in collision frequency with solar activity in the lowest ionosphere (at about 60 km height). In this communication we direct attention to similar results which we have obtained for a somewhat higher altitude (about 110 km).

In 1960–62 we carried out a series of vertical incidence absorption measurements using pulse signals on frequencies in the range 1·9–4·0 Mc/s. The measurements were made near local noon and at this time the absorption on 1·9 Mc/s was always predominantly 'non-deviative' (*D*-region). Simultaneously with those on 1·9 Mc/s, absorption measurements were also made on 2 frequencies just below, and 2 frequencies just above, the normal region *E* critical frequency (*foE*). At these latter frequencies the observed absorption was predominantly of the 'deviative' type associated with considerable group retardation. Expanded scale ionograms were available at the times of these measurements and from these the appropriate *E*-layer electron density/height profiles were calculated. These $N(h)$ profiles and the experimental measurements of absorption on the 5 frequencies were then used to calculate a best-fit collision frequency/height profile. Reliable results were obtained on 47 days during the whole period of the measurements, and it was found that theory and experiment could only be satisfactorily reconciled if the collisional frequency at *E*-layer heights varied by quite a large factor from day to day.

Fig. 1 shows the daily values of ν at a true height of 110 km, deduced from this work, plotted against the 10-cm solar radio wave flux. It will be seen that there is a fairly clear positive correlation between the two parameters. The slope of the best line to fit in Fig. 1 represents a change of about 1 per cent in ν at 110 km per unit change in the flux φ. We consider that part of this apparent change in ν with solar activity may be due to a change in *D*-region ionization with solar activity and the true change is probably smaller than the figure quoted.

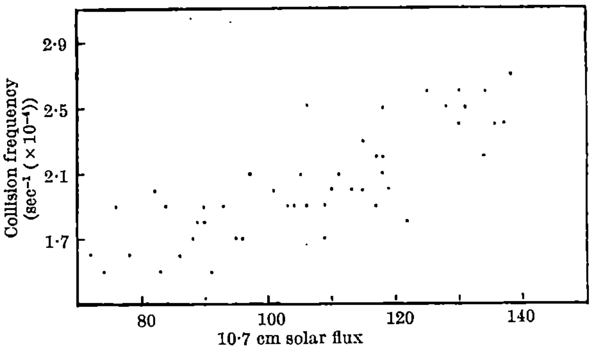

Fig. 1. Variation of collision frequency at 110 km with the 10·7 cm solar flux

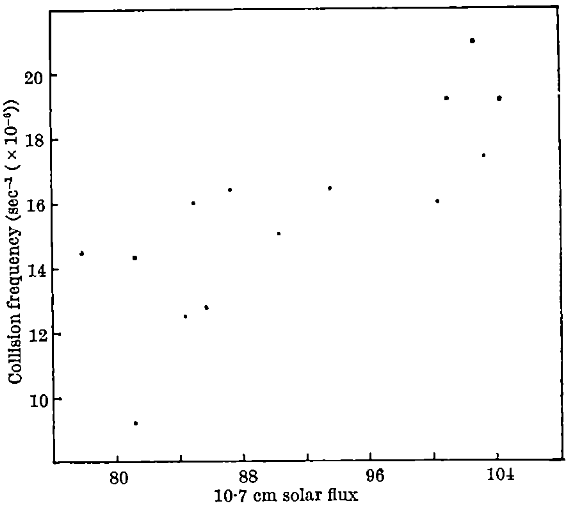

Fig. 2. Variation of collision frequency at 59·5 km with the 10·7 cm solar flux (ref. 1)

In Fig. 2 the values of ν given by Belrose and Hewitt for a height of 59·5 km are also plotted against 10 cm solar flux. The rate of increase of ν at this height is about 2 per cent per unit change in φ. The first published evidence for a dependence of ν on solar activity was given by Schlapp[2], and his results indicate that at a height of about 110 km ν changes by rather less than 1 per cent per unit change in φ.

Some data on collision-frequency measurements made in India have been published by Ramana and Rao[3] and provide supporting evidence for this dependence of ν on solar activity. These workers give values of ν at the peak of the *E* layer for each month in the period March 1958–November 1959. We have made some first-order corrections to these results to give estimates of ν at a fixed height, and find that for an altitude of about 105 km there is again evidence for an increase in collision frequency with solar activity of the same order of magnitude as that deduced here.

There are thus three independent sets of data showing a significant positive dependence of the *E*-layer electron collision frequency on solar activity. Various authors have suggested modifications of the usual Appleton–Hartree magneto-ionic theory to take account of the dependence of the collisional cross-section on the electron energy. Consideration of the collision frequencies deduced from the present work indicates that at 110 km the electron temperature at noon may exceed the neutral gas temperature by a factor of about two.

Disappointing Interim Palæomagnetic Results from the Seychelles

RECENT seismic refraction experiments made in connexion with the International Indian Ocean Expedition have confirmed that the shallow Seychelles Bank has crustal structure of a continental type and represents an isolated continental fragment in the middle of the north-west Indian Ocean[1,2]. The late Precambrian granites exposed on the central islands of the Seychelles group have been shown to be cut by two sets of dolerite dykes which are of a Precambrian and early Tertiary age, respectively[3,4].

Du Toit and other writers have suggested that the Seychelles represent a fragment left behind during the break-up of Gondwanaland[5], and it is clear that this hypothesis is now in need of testing. Accordingly, in November 1963 (ref. 2) we collected 71 orientated specimens from 40 different dykes, sampling all the more accessible dykes shown on Mr. B. H. Baker's geological map[4] on the islands of Mahé, Praslin, Cousin, La Digne, Felicité and Marianne. The natural remanent magnetization directions of these specimens have been measured by one of us (T. A. R.) using an astatic magnetometer in Nairobi. The results are widely scattered and strongly suggest that the rocks are unstable. It is to be hoped that the a.c. demagnetization and thermal 'washing' techniques, which are now being tried, will reveal a significant grouping of the magnetic vectors.

This disappointing preliminary result would certainly not warrant publication in the normal course of events. However, the Seychelles are of current interest in connexion with the International Indian Ocean Expedition, and as this experiment is a particularly obvious one, we imagine that other groups are likely to consider going to these remote islands to collect palæomagnetic material. We wish them better luck than we have had.

Heights of Central Absorbing Regions for a Strong Auroral Absorption Event at Lower Latitude

ABNORMAL ionospheric absorption of cosmic radio noise has been investigated at Moscow (46° 44′ N., 117° 00′ W.), Idaho, U.S.A., since September 1962. Observations are being made by three riometers operating at the frequencies of 20, 30 and 40·25 Mc/s.

The majority of abnormal absorption events obtained occurred prior to the International Years of the Quiet Sun. Five types of absorption were positively identified. They are sudden commencement absorption, sudden cosmic noise absorption, auroral absorption, sunset absorption and sunrise absorption.

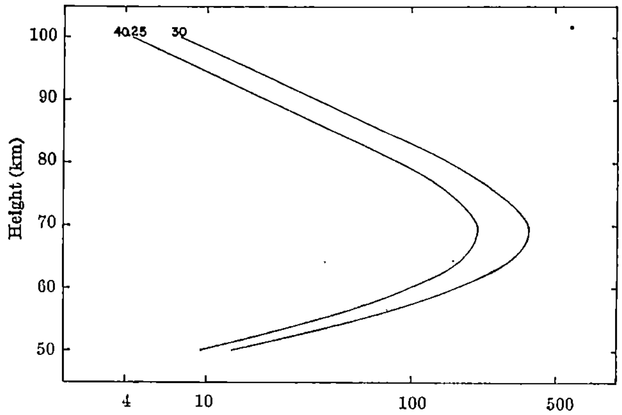

Fig. 1. Relaxation time as a function of height

One phase of the investigations included height determinations of the central absorbing regions for a strong auroral absorption event at lower latitude. This communication reports the heights of central absorbing regions for the strong auroral absorption events of September 22, 1963, which were deduced by utilizing the relaxation time method introduced by Ziauddin[1]. This method relies on the fact that the absorption (expressed in db) suffered by a radio wave in the lower ionosphere is proportional to the number of electrons encountered in the absorbing region and is a function of the collisional frequency of the electrons.

The electronic collisional frequencies, ν at various heights, were calculated from the following formula given by Nicolet[2]:

$$\nu = 5{\cdot}4 \times 10^{-10}\, nT^{1/2} \qquad (1)$$

Height distributions of n (number density of the atmospheric constituents) and T (atmospheric temperature) were adopted from the *U.S. Standard Atmosphere*, 1962 (ref. 3), which is an idealized, middle-latitude year-round mean over the range of solar activity between sunspot minimum and maximum. The calculated values of ν are given in Table 1.

Following Ziauddin's assumptions, the effective electron densities at various heights for the observing frequencies of 30 Mc/s and 40·25 Mc/s were determined from the following well-known equation:

$$A(\text{db}) = 0{\cdot}46 \int \frac{N\nu}{(w + w_2)^2 + \nu^2}\, dS \qquad (2)$$

The symbols used in equation (2) have usual meanings.

The effective electron densities at various heights were then combined with the corresponding recombination rates α given by Moler[4] to calculate the ionospheric relaxation times ($T = 1/2\alpha N$ sec) at various heights. The calculated relaxation times were plotted as a function of height in Fig. 1. Figs. 2 and 3 respectively show simultaneous strong auroral absorption events of September 22, 1963 (120° W.M.T.), observed at the frequencies of 30 Mc/s and 40·25 Mc/s. Heights deduced from Fig. 1 for 30 Mc/s events are in the range of 79–86 km, while for 40·25 Mc/s they are in the range of 72–78 km. The 40·25 Mc/s waves were absorbed at lower heights than the 30 Mc/s waves as predicted by magnetoionic theory. For 30 Mc/s events, heights of central absorbing regions are somewhat higher than those reported at higher latitudes[5]. For both 30 and 40·25 Mc/s events, there was a tendency for successive absorption onsets to progress toward lower heights. Ziauddin and Forsyth[5] also found a similar tendency.

It should be noted that the relaxation-time method is subject to certain criticisms, but for a first approximation

Table 1. THE ELECTRON COLLISIONAL FREQUENCY

GEOCHEMISTRY

Content of Lead in the Earth's Initial Chondrite-like Oxide Mass and the Partition Coefficient of Lead for Crystallization of Silicate Melt

From the isotopic composition of lead in ores, the following empirical formula was obtained[1]:

$$\log (C_U/C_{204}) = 0{\cdot}503 \log (C_{Th}/C_{204}) + 0{\cdot}231 \qquad (1)$$

where C_U, C_{Th} and C_{204} stand for the weight concentration of uranium, thorium and lead-204 in the material of source from which common leads of ores were derived. The purpose of this communication is to treat this formula from the aspect developed in recent investigations[2-4] of the geochemistry of lanthanides and to extract some numerical information therefrom.

The same reasoning and mathematical treatment as presented in discussion[2-4] of lanthanide geochemistry will lead to the following theoretical formulæ by analogy.

$$\log C_{Th} = \log C^0{}_{Th} - (1 - k_{Th}) \log f_w \qquad (2)$$

$$\log C_U = \log C^0{}_U - (1 - k_U) \log f_w \qquad (3)$$

$$\log C_{Pb} = \log C^0{}_{Pb} - (1 - k_{Pb}) \log f_w \qquad (4)$$

where C_{Th}, C_U and C_{Pb} are the concentrations of thorium, uranium and lead in a liquid-type material such as basalt, $C^0{}_{Th}$, $C^0{}_U$ and $C^0{}_{Pb}$ are the concentrations of thorium, uranium and lead in average chondritic oxide mass which is assumed to be nearly equal to the source material of the Earth's oxide sphere, k_{Th}, k_U and k_{Pb} are the partition coefficients for thorium, uranium and lead, and f_w the value of liquid fraction for the concerned material. These equations (2), (3) and (4) are derived from a rather rough, but necessary, assumption that the partition coefficients of minor elements between the just-formed crystals and the coexisting silicate melt are constant during the whole process of solidification of melt. Therefore, the partition coefficients to be obtained from the foregoing equations should be regarded as mean values for the overall process.

From equations (2), (3) and (4), we get:

$$\log (C_{Th}/C_{Pb}) = \log (C^0{}_{Th}/C^0{}_{Pb}) - (k_{Pb} - k_{Th}) \log f_w \qquad (5)$$

$$\log (C_U/C_{Pb}) = \log (C^0{}_U/C^0{}_{Pb}) - (k_{Pb} - k_U) \log f_w \qquad (6)$$

Eliminating $\log f_w$ from equations (5) and (6) leads to[7]:

$$\log (C_U/C_{Pb}) = b \log (C_{Th}/C_{Pb}) + \log (C^0{}_U/C^0{}_{Pb}) - b \log (C^0{}_{Th}/C^0{}_{Pb}) \qquad (7)$$

where:

$$b = (k_{Pb} - k_U)/(k_{Pb} - k_{Th}) \qquad (8)$$

Comparison of these theoretical formulæ (7) and (8) with the empirical one (1) provides the equations :

$$0{\cdot}503 = (k_{Pb} - k_U)/(k_{Pb} - k_{Th}) \qquad (9)$$

$$0{\cdot}231 = \log (C^0{}_U/C^0{}_{204}) - 0{\cdot}503 \log (C^0{}_{Th}/C^0{}_{204}) \qquad (10)$$

As the partition coefficients k_{Th} and k_U have been estimated[5] to be 0·0733 and 0·182, respectively, the partition coefficient k_{Pb} is calculated to be 0·292 from equation (9). On the other hand, since $C^0{}_U$ and $C^0{}_{Th}$ are 0·0168 (refs. 5 and 6) and 0·048 p.p.m. (refs. 5 and 7), respectively, $C^0{}_{204}$ is estimated to be 0·00199 p.p.m. from equation (10). As the present-day isotopic fraction of lead-204 relative to the whole lead is about 1/72, and the atomic weight of lead is about 207, the concentration of whole lead in the Earth's initial chondrite-like oxide material in reference to the present time can be evaluated to be 0·145 p.p.m. (= 0·00199 × 72 × 207/204). It is intriguing that this value coincides with the average content of lead, 0·15 p.p.m. (ref. 6), in ordinary hypersthene-bronzite chondrites. But both carbonaceous chondrites and enstatite chondrites have much higher concentrations of lead, 1·5–4·2 p.p.m. (ref. 6). Since carbonaceous chondrites are inferred to contain nearly the cosmic abundances[8,9] of elements excepting highly volatile ones, the abundance estimated here will indicate that the major part of lead on the Earth has been incorporated into the Earth's core. If the initial overall content of lead for the Earth was comparable with that of ordinary chondrites, the foregoing result would suggest that any selective enrichment of lead in the Earth's metallic core did not occur.

Finally, a comment can be added in connexion with the partition coefficient obtained above, 0·292, for lead. The volcanic rocks belonging to the pigeonitic rock series[10] of Izu-Hakone area, Japan, were suggested to be tholeiites and their immediate derivatives, and the volcanic rocks of the hypersthenic rock series[10,11] of the same area to be the products from high-alumina basalt through contamination. At this point let us review the data on isotopic ratios and concentration[11] of lead in the rocks of these

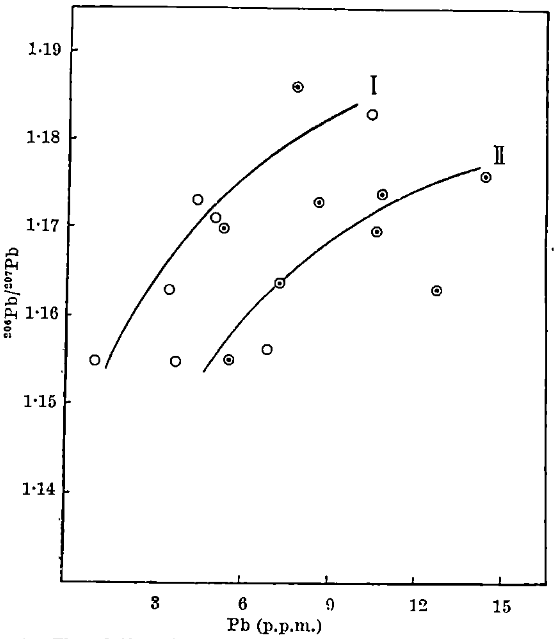

Fig. 1. The relationship between the isotopic ratio ^{206}Pb/^{207}Pb and the concentration of lead (ref. 11). ○, Pigeonitic rock series; ⊙, hypersthenic rock series

two series. It is noteworthy (see Fig. 1) that the concentration ratio of curve I to curve II for the same and smaller isotopic ratios ^{206}Pb/^{207}Pb appears to be roughly comparable with the partition coefficient estimated for lead. This suggests that the tholeiite and the high-alumina basalt could stand in the conjugate relation of solid and liquid (or crystal and melt) to each other, apart from the genetic sequence. Accordingly, this might give rise to the inference that the high-alumina basalt is a product of partial melting of the rock equivalent to tholeiite, or alternatively that the tholeiite is a product which was once separated as aggregate of crystals from the magma resembling a high-alumina basalt in composition. Since the thorium/uranium ratio, 4·0 (ref. 11), estimated from the isotopic composition of lead is nearly consistent with the ratios, 3·5–3·9 (ref. 12), actually observed in high-alumina basalts but in contrast to the corresponding ratios, 1·5–1·7 (ref. 12), observed in tholeiite, the latter inference gains support.

Chlorine-36 produced by Neutron Capture in Meteorites

THE existence of the long-lived radionuclide chlorine-36 in iron meteorites, where it is produced by the spallation of the metal during its exposure to cosmic rays in space, is now well known. The measurements of cosmogenic ^{36}Ar and ^{36}Cl so produced permit one to calculate the so-called cosmic-ray exposure age of a meteorite. In this communication the results of experiments which show that in large iron meteorites the production of this nuclide also takes place via the reaction ^{35}Cl$(n,\gamma)^{36}$Cl on the lawrencite inclusions in the metal are presented. This result is of significance in deducing the history of meteorites from the investigation of cosmic-ray reaction products.

The experiments were carried out on a 2-kg slice of Canyon Diablo meteorite (U.S. National Museum No. 676) provided by Dr. E. P. Henderson. A 400-g piece from the metal was sawed off, cleaned, and dissolved in 8 M nitric acid in a closed system. ^{36}Cl was measured by techniques described earlier[1,2]. This measurement gave ^{36}Cl produced by both the spallation and the neutron-capture processes. For the next measurement, the main slice was cleaned in dilute nitric acid, and some chips were removed from it on a mechanical scraper using a tungsten carbide tool. These meteorite chips, weighing 248 g, were immersed in 1,000 ml. 0·5 M nitric acid and heated to boiling. The acid was decanted. Two more similar washings with fresh acid were carried out. From the combined washes silver chloride was precipitated and the ^{36}Cl was measured by the usual method.

Table 1. DATA ON ^{36}CL MEASUREMENTS IN CANYON DIABLO*

Specimen	Intact metal	Metal chips
Mass (g)	399·0	248·0
Natural Cl mass fraction (%)	0·0083	0·0357
Initial counts		
Chemical yield (%)	79·2	58·2
Background rate (c.p.m.)	0·228 ± 0·007	0·205 ± 0·007
Net sample rate (c.p.m.)	0·302 ± 0·019	0·085 ± 0·011
S (^{36}Cl) (d.p.m./kg)	3·21 ± 0·21	2·67 ± 0·34
Recycle counts		
Chemical yield (%)	52·6	49·2
Background rate (c.p.m.)	0·199 ± 0·007	0·182 ± 0·008
Net sample rate (c.p.m.)	0·183 ± 0·014	0·067 ± 0·014
S(^{36}Cl) (d.p.m./kg)	2·78 ± 0·21	2·45 ± 0·51
Average S(^{36}Cl) (d.p.m./kg)	3·0 ± 0·2	2·6 ± 0·3
Neutron-capture S(^{36}Cl) (d.p.m./kg metal)	0·6 ± 0·2	2·6 ± 0·3
Neutron-capture S_T(^{36}Cl) (d.p.m./g Cl)		7·3 ± 0·8
Spallation S(^{36}Cl) (d.p.m./kg metal)	2·4 ± 0·2	—

* S(^{36}Cl) = specimen specific ^{36}Cl activity.
S_T(^{36}Cl) = target-element specific ^{36}Cl activity.
c.p.m. = counts per minute.
d.p.m. = disintegrations per minute.

The experimental results are presented in Table 1. The standard deviations of the final results are somewhat larger than the statistical errors of counting because of various other sources of uncertainty; for example, non-uniformity of source deposition, etc.

The treatment of the metal chips with a total of 1·5 mol nitric acid should dissolve less than about 20 g of the specimen. The ^{36}Cl found in the washings of the chips is therefore not produced from the spallation of the metal. It is clearly associated with the easily washable natural chlorine, and is therefore produced in it by the (n,γ) process.

We assume that the production of ^{36}Cl by both the processes—spallation and neutron-capture—is uniform throughout our specimen, and calculate that the specimen specific activity of ^{36}Cl produced by spallation is $(2·4 \pm 0·2)$ d.p.m./kg metal, and that the ^{36}Cl produced by the neutron process is $(7·3 \pm 0·8)$ d.p.m./g Cl. Large variation in the ^{36}Cl activity within the slab is not expected, since the low specimen specific activity suggests that the specimen must have come from the deep interior of the meteoroid where the depth distribution of ^{36}Cl should be rather 'flat'[2].

Another radionuclide which is expected to be produced by the (n,γ) reaction is ^{59}Ni. Its target-element specific activity in our specimen is[3] $(0·30 \pm 0·07)$ d.p.m./g nickel. If both the nuclides ^{59}Ni and ^{36}Cl were produced by the capture of thermal neutrons, a value of 19 would be expected for the ratio $S_T(^{36}\text{Cl})/S_T(^{59}\text{Ni})$. The observed value is 24 ± 6. The agreement of the two numbers is probably accidental, since a complete thermalization of neutrons is not expected in even a moderately large meteoroid[4]. Detailed calculations on neutron production have been made for stone meteorites by Eberhardt, Geiss and Lutz[4]. These authors have also discussed the application of such investigations to the question of the size of the meteoroid and the problem of space erosion.

The presence of neutron-capture ^{36}Cl which can be washed away from the chips points to a possible source of uncertainty in calculations of the cosmic-ray exposure ages of iron meteorites. The experimental results that are used for those calculations are the ^{36}Ar concentration and ^{36}Cl specific activity in adjacent specimens. Generally the latter is measured by dissolving a compact mass and includes both the spallation and the neutron-capture ^{36}Cl. The ^{36}Ar is measured on a small metal chip after thorough cleaning. Any ^{36}Ar resulting from the decay of the neutron-capture ^{36}Cl would reside with the natural chlorine and would probably be removed during sample preparations. This would result in a low value for the ^{36}Ar concentration and hence in a low value for the apparent cosmic-ray exposure age of the meteorite.

I thank Prof. Truman P. Kohman for his advice. The meteorite was kindly donated by Dr. Edward P. Henderson. This work was supported by the U.S. Atomic Energy Commission contract *AT*(30–1)–844.

METALLURGY

Oxygen Diffusion in Tungsten

Information concerning oxygen diffusion in tungsten is technologically valuable for many reasons. One such reason is its important role in the development of the structural properties of tungsten for high-temperature applications.

Because direct measurements are difficult, indirect assessments of oxygen diffusion in tungsten have recently been made, but the results seem somewhat confusing. For example, assuming the frequency factor Do as 10^{-2} cm²/sec, Stringer and Rosenfield[1] estimated the activation energy for oxygen diffusion in tungsten as 2·7 eV by using Cottrell's equation which was established on the basis of the Portevin–Le Chatelier effect. This value of activation energy agrees with those for oxygen diffusion in some transition metals in which the solubility of oxygen is smaller than 1 per cent. On the other hand, Jacobs[2] obtained a value of the frequency factor as 1·3 cm²/sec and the activation energy as 24,000 cal/mol for oxygen diffusion in tungsten by means of internal friction measurements. His results agree with those for oxygen diffusion in some transition metals in which the solubility of oxygen is greater than 1 per cent. Regardless of the empirical relation between diffusion and solubility for oxygen in transition metals, the two estimations yield serious disagreement on the rates of oxygen diffusion in tungsten.

The purpose of this communication is to deduce a diffusion coefficient of oxygen in tungsten at a convenient temperature from a direct measurement of the variation of oxygen concentration with time of diffusion and to compare with the estimations mentioned previously.

Examining the effect of the interstitial impurities on the recrystallization of tungsten, Allen, Maykuth and Jaffee[3] doped high-purity tungsten crystals with oxygen by means of a diffusion process. In their experiment, the boundary condition of the diffusion equation for diffusant from a constant surface concentration into an infinite cylinder is closely fulfilled. Although the experimental uncertainties due to the analytical procedure appeared for single crystalline specimens, the variation of the dopant concentration with time for polycrystalline specimens seems meaningful, that is, the average concentration of oxygen in tungsten is 33 p.p.m. for 6 h of diffusion at 1,700° C and 39 p.p.m. for 12 h at the same doping condition. Should the most reliable value of the solubility of oxygen in tungsten at 1,700° C be about 40 p.p.m.[3,4], the fractional saturation from the doping process is about 83 per cent for 6 h and 98 per cent for 12 h. Knowing the dimensions of the polycrystalline specimens, the diffusion coefficient of oxygen in tungsten can be estimated as 3×10^{-7} cm²/sec at 1,700° C. From the results of the single crystalline specimens, the diffusivity is calculated to have a value between 7×10^{-8} cm²/sec and 5×10^{-7} cm²/sec at the same temperature.

According to the Arrhenius relation for the temperature dependence of diffusivity, the diffusion coefficient of oxygen in tungsten at 1,700° C can also be assessed from the other two estimations of the activation energy and the frequency factor. The values are 3×10^{-3} cm²/sec and 1×10^{-9} cm²/sec from the internal-friction measurements and the Cottrell's equation respectively. Because of the serious disagreement of these two estimations, one should make an approximation based on the observations from the dosing experiment. Should 3×10^{-3} cm²/sec be the expected value, the time for saturation with oxygen at 1,700° C would take as short as 0·5 min. It is obvious that this value is too large for the diffusivity at the temperature. On the other hand, 1×10^{-9} cm²/sec would be too small for dosing to about 90 per cent of saturation within a few hours. It is therefore our opinion that the D value should be of the order of 10^{-7} cm²/sec at 1,700° C as estimated from the dosing experiment.

Decomposition Pressure Hysteresis in the Zirconium-Hafnium-Hydrogen System

A recent investigation[1] of the Zr–Hf–H equilibrium system at pressures less than one atmosphere of hydrogen gas revealed the presence of hysteresis. Although this was not unexpected[2], it was somewhat disconcerting and demanded further elucidation. Results presented here will show that: (1) decomposition pressure hysteresis must be considered when dealing with equilibrium between gases and multi-component alloy systems; (2) hysteresis always involved a region of more than one phase and was most prominent at lower temperatures where diffusion was slowest; (3) no evidence for an interfering surface film was found; (4) internal factors such as stress and large surface area accompanying a martensitic reaction are prominent in the hysteresis reactions of the Zr–Hf–H system.

Hysteresis in metal–hydrogen systems has been found by a number of workers as far back as the early 1900's, and the subject has been reviewed in recent publications[3–7]. Most explanations involved internal solid-state properties of the hydrided alloys. On a pressure-composition plot different paths were followed on absorbing or desorbing hydrogen when crossing a multi-phased region because either: (1) the two paths represented different statistically predictable metastable states of long duration; or

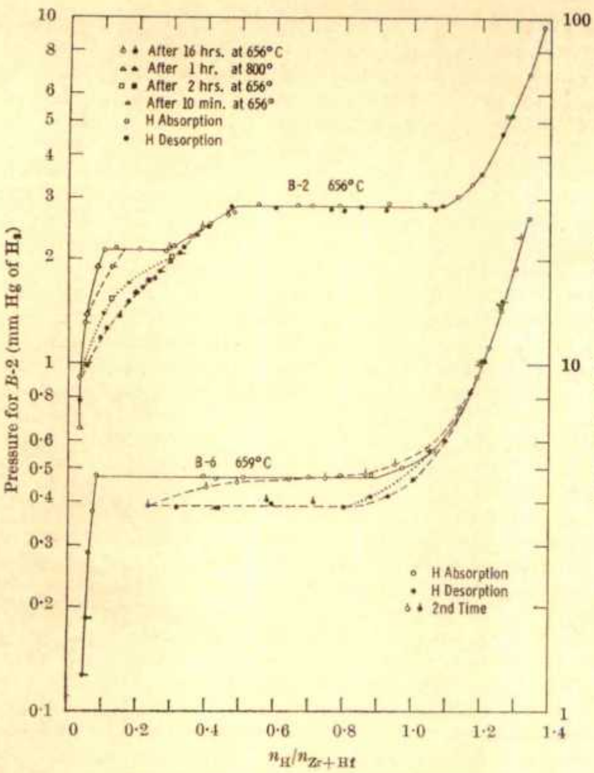

Fig. 1. Hysteresis in the Zr–Hf–H system

(2) the phase rule had introduced into it another variable, such as elastic restraint and long-range ordering; or (3) the repositioning of metal atoms particularly by diffusion was extremely and unobservably slow; or (4) the barrier to nucleation was very great; or (5) the presence of plastic deformation caused complicated volume changes which were irreversible. In addition, some results have shown that a surface film could form during absorption or afterwards so as to restrict the subsequent desorption of hydrogen from the metal. For the Zr–Hf–H system, approach to equilibrium curves was always rapid at first, tapering off exponentially, as expected; and, furthermore, no structural evidence was found for a limiting film on any of the processed specimens.

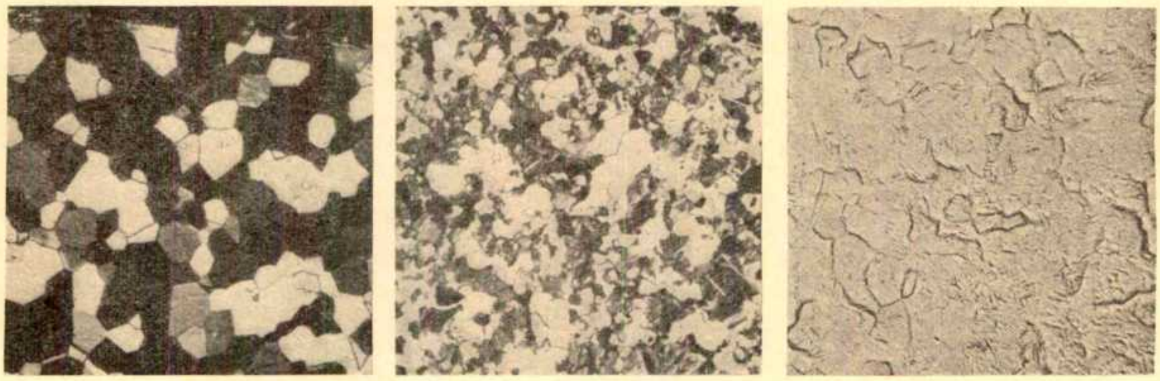
Fig. 1 shows the details for the two alloys *B*-2 (Zr + 37 w/o Hf) and *B*-6 (Zr + 73 w/o Hf) at approximately the same temperature. The aim of such a detailed investigation was to show that some inhomogeneity was present in the metal which could not be easily removed at the temperature of reaction with hydrogen. Open and closed, unmarked circles represent the first tracing of the isotherm with the previously unreacted alloy. Data points were obtained by the use of a high-sensitivity microgravimetric apparatus, previously described[2,8].

As seen in Fig. 1 for the *B*-2 alloy, removal of hysteresis was indeed dependent on time, being easier the higher the temperature and longer the time of pretreating the sample before rehydriding. Hysteresis then was essentially a memory-sensitive process where the effects of previous treatments could remain and influence future hydriding. The *B*-6 isotherm also showed the inability to retrace the original isotherm without some intermediate annealing treatment. Here, for the only time in the investigation, the descending pressure isotherm showed a hysteresis plateau.

Since hysteresis always involved a multiphase region, it was reasonable to assume that the larger metal atoms could not diffuse back after nucleation of the hydride(s) to the equilibrium positions they maintained on the ascending pressure curve. Hence, the hydride(s) in the β- or γ-regions which precipitated with increase in hydrogen content lost all their hydrogen on decreasing the pressure only if the hydride metal atoms redissolved into the lattice. The diffusion coefficients of zirconium and hafnium in the zirconium–hafnium alloys would then govern the appearance of hysteresis. With both hafnium and zirconium in solution in the hydride phase, as proved by electron microprobe analyses, the interactions between the two could well reduce the diffusion coefficients of either below that in the pure metal. This would make hysteresis more prominent in multiple metal atom–hydrogen alloys. An appreciable rise in temperature (150° C for *B*-2) increased the metal atom diffusion rate more than 2 orders of magnitude and restored the initial state of the lattice. The diffusion coefficient of hydrogen at the reactive temperature was already much greater than necessary to reach equilibration in the times used.

In an effort to determine the type of diffusion barriers which existed, a structural analysis of a hydrided and dehydrided *B*-6 alloy was conducted. This alloy was hydrided to one atmosphere of hydrogen pressure at 752° C and dehydrided through a hysteresis loop between the α- and γ-regions. The absorption isotherm was similar to *B*-6 in Fig. 1, but the desorption portion sloped with removal of hydrogen.

Fig. 2 shows the microstructural effects after complete dehydriding. The highly fragmented grains in (*b*) are seen as evidence for the previous coexistence of the hexagonal phases of the α-region and the hydrided colonies of the γ-region. In fact, not only had grain fragmentation occurred, but also a general grain roughening resulted as shown by the needle-like structure. Such a structure is reminiscent of martensitic transformations. The macro result was a specimen with a dull matt surface finish. Further evidence for a difference in initial and dehydrided specimen structures was the following: (1) the aforementioned dehydrided alloy, which was still reasonably



a *b* *c*

Fig. 2. **Structural** effects of hydriding. *a*, Etched sample of annealed, unhydrided *B*-6 alloy-polarized light (× *c* 140); *b*, same after hydriding + dehydriding – polarized light (× *c*. 140); *c* as *b*, normal light (× *c*. 350)

ductile, had a hardness of 150 Vicker's pyramid number compared with 115 Vicker's pyramid number for the initial material; (2) an X-ray powder pattern gave five lines for a face-centred-cubic of $a_0 = 4{\cdot}61$ Å although the alloy should have been entirely hexagonal. All 23 other lines of this pattern did index as hexagonal with c/a ratio nearly that of the parent B-6 alloy. Strain in the cubic phase was shown by a lattice parameter lower than the expected 4·72 Å from an equilibrium, fully hydrided, cubic B-6 alloy. The volume of the hydride with the smaller parameter was intermediate between the hexagonal B-6 lattice and the expected hydride, being additional evidence for a slow structural change of the hydrides back to the initial material.

In conclusion, it is seen that decomposition pressure hysteresis in the Zr–Hf–H system is intimately connected with a slow-diffusion process controlled by structural features, most likely of a martensitic nature. This connexion has been drawn recently for other than hydrogen systems, notably cobalt[9] and zirconia[10]. With an appreciation of the hysteresis phenomena, it was then possible to derive meaningful and consistent thermodynamic functions for the Zr–Hf–H system.

CHEMISTRY

Hydroxyl Ions in the Mass Spectrum of Water Vapour

We have investigated the existence of stable primary OH^- ions in the negative ion mass spectrum of water vapour. Mann, Hustrulid and Tate[1] specially looked for OH^- ions in their mass spectrometric investigation of the ionization and dissociation of water vapour but found none. On the basis of this evidence Laidler[2] suggested extremely stable electronic configurations for the stable states of the OH^- ion which would be strongly repulsive to an approaching hydrogen atom. The hydrogen would thus play no part in the electronic excitation.

However, Cottin[3] has carried out a similar investigation and has found three types of OH^- ions; two of these are secondary products and are formed by electrons with energies between 5 and 12 eV. The ion which appears at 16 eV seems to be a primary ion. Cottin suggests that the three types of OH^- ions are produced in the following way:

$$H^- + H_2O \rightarrow OH^- + H_2$$
$$O^- + H_2O \rightarrow OH^- + OH$$
$$H_2O + e^- \rightarrow OH^- + H^+ + e^-$$

The pressure of water vapour in Cottin's work was about 10^{-2} torr in the ion source and the formation of secondary ions is readily understood. The presence of the primary ion could well have been due to collision stabilization of energy-rich states of OH^-.

We have converted an A.E.I. *MS2SG* mass spectrometer for the investigation of negative ions by reversing the appropriate electrical connexions and increasing the sensitivity by using a 100-kMohm grid leak in the electrometer detector instead of the usual 20 kMohm. Source pressures were about 10^{-4} torr to reduce any contribution from energy-rich states. OH^- ions appeared at 17·5 eV and the $OH^- : O^-$ ratio at 70 eV was 0·051. The negative ion mass spectrum of methanol has been investigated by Melton and Rudolph[4], and we repeated this work to check the mass spectrometer and aid the identification of the OH^- ions. The value for the ratio $OH^- : O^-$ was 0·213 and we found 0·235. However, our ratio $O^+ : O^-$ from O_2 was about 280 while theirs was about 43. Thus there seems to be much more discrimination against negative ions in our mass spectrometer. This is probably because negative ions are generally formed with appreciable kinetic energy and the mass spectrometer discriminates against them. This discrimination varies from instrument to instrument, and it may be the reason why Mann *et al.* were not able to detect any OH^- ions (particularly with pressures about 10^{-4} torr in the analyser).

The formation of OH^- means that the formation of O^- in the electron impact dissociation of water can still be due to the dissociation of OH^-. For the dissociation:

$$OH^- \rightarrow O^- + H$$

the appearance potential of O^- is given by the relation:

$$A(O^-) = D(OH^-) - EA(O) + \Sigma_E$$

where $D(OH^-)$ is the dissociation energy of OH^-, $EA(O)$ is the electron affinity of O and Σ_E is the energy contribution from the kinetic and electronic states of O and H. Now $D(OH^-) = D(OH) + EA(OH)$, where $D(OH)$ is the dissociation energy of OH and $EA(OH)$ is its electron affinity. Substituting this in the aforementioned relation and using the values of $D(OH)$, $EA(OH)$ and $EA(O)$ given in the literature[5–7], we get $A(O^-) = 4{\cdot}34 + 2{\cdot}65 - 1{\cdot}45 + \Sigma_E = 5{\cdot}54 + \Sigma_E$. Now $A(O^-)$ for one of the O^- species has been determined to be 7·4 eV. This leaves a not unreasonable amount of energy distributed between the different kinetic and electronic states of O^- and H.

The appearance of OD^- formed as a primary ion has been also observed by us. It appears at 18·1 eV and has an OD^-/O^- ratio of 0·065 at 70 eV.

Disproportionation of Halogenated Alkyl Radicals

When 1,3-dichlorotetrafluoro acetone is photolysed, two CF_2Cl radicals and a molecule of carbon monoxide are formed. The CF_2Cl radicals combine to form 1,2-dichlorotetrafluoro ethane, and abstract chlorine atoms from the parent ketone to form dichlorodifluoro methane[1]; but, in addition to these products, a significant amount of 1,3-dichlorohexafluoro propane is found in the photolysis mixture. At first it was considered that this arose from a secondary photolysis of 1,4-dichlorohexafluoro acetone formed as a result of the chlorine abstraction reaction, but quantitative investigations[2] showed that it could not originate in this way.

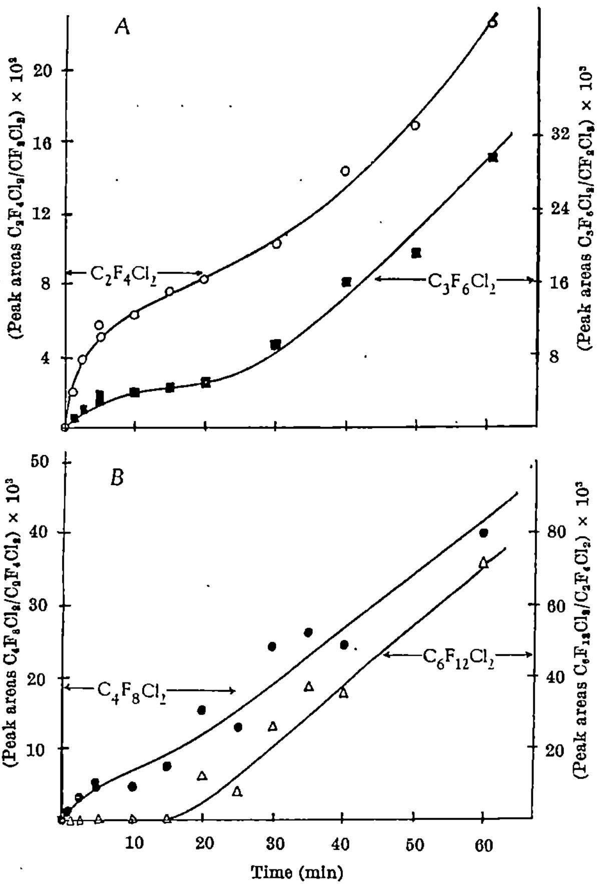

Fig. 1. Yields of products against time

It was suggested instead that the 1,3-dichlorohexfluoro propane was formed by the combination of CF_2Cl and CF_2CF_2Cl radicals. The CF_2CF_2Cl radicals were presumed to arise from a combination of CF_2Cl radicals with CF_2 radicals produced as a result of a disproportionation reaction:

$$2CF_2Cl \rightarrow CF_2 + CF_2Cl_2$$
$$CF_2 + CF_2Cl \rightarrow CF_2CF_2Cl$$
$$CF_2CF_2Cl + CF_2Cl \rightarrow ClCF_2CF_2CF_2Cl$$

There was little direct experimental evidence to support this suggestion other than the demonstration that the dichlorodifluoro methane detected in the system was formed by two distinct processes and the isolation of small quantities of 1,4-dichlorooctafluoro butane as a result of the dimerization of CF_2CF_2Cl radicals. In particular, no tetrafluoro ethylene was ever detected in the photolysis products, and it would have been expected to occur by the dimerization of CF_2 radicals.

Some support for the hypothesis was given by the demonstration by Gunning[3] of the occurrence of 1,3-dichlorohexafluoro propane in the products of the mercury photosensitization of dichlorodifluoro methane. In addition, the reactions observed by Mastrangelo[4] with CF_3 radicals could only be satisfactorily explained by assuming that CF_3 radicals also disproportionate.

Because of the ambiguous nature of the evidence from the mercury photosensitized decomposition of CF_2Cl_2, it was investigated in greater detail. The primary act was most probably the production of CF_2Cl radicals:

$$Hg^* + CF_2Cl_2 \rightarrow CF_2Cl + HgCl$$

since it has been demonstrated that mercury is consumed in the reaction. There is a possibility that 1,3-dichlorohexafluoro propane arises as a result of the photodecomposition of 1,2-dichlorotetrafluoro ethane produced by the combination of CF_2Cl radicals.

$$ClCF_2CF_2Cl + Hg^* \rightarrow CF_2CF_2Cl + HgCl$$
$$2\ CF_2CF_2Cl \rightarrow ClCF_2CF_2CF_2CF_2Cl$$
$$CF_2CF_2Cl + CF_2Cl \rightarrow ClCF_2CF_2CF_2Cl$$

If this were the case, then it would be anticipated that there would be a perceptible induction period in the formation of 1,3-dichlorohexafluoro propane, while sufficient dichlorotetrafluoro ethane accumulated in the system to compete with the CF_2Cl_2 for the quenching of excited mercury atoms. In Fig. 1*A*, the yields of 1,2-dichlorotetrafluoro ethane and 1,3-dichlorohexafluoro propane are plotted against irradiation time. It can be seen that there is no induction period and this behaviour can be contrasted with that illustrated in Fig. 1*B*. Here, 1,2-dichlorotetrafluoro ethane has been submitted to mercury photosensitization alone and the yields of the two main products formed are plotted against irradiation time.

$$ClCF_2CF_2CF_2CF_2Cl + Hg^* \rightarrow CF_2CF_2CF_2CF_2Cl + HgCl$$
$$CF_2CF_2CF_2CF_2Cl + CF_2CF_2Cl \rightarrow ClCF_2CF_2CF_2CF_2CF_2CF_2Cl$$

Here there is a long induction period in the formation of 1,6-dichloroduodecafluoro hexane due to the slow accumulation of 1,4-dichlorooctafluoro butane in the reaction system.

This suggests that the 1,3-dichlorohexafluoro propane obtained in the mercury photosensitization of CF_2Cl_2 is not formed by a secondary photosensitization of 1,2-dichlorotetrafluoro ethane, but arises as a result of some more rapid process such as the disproportionation of CF_2Cl radicals. In order to confirm this observation, varying amounts of 1,2-dichlorotetrafluoro ethane were added to CF_2Cl_2 before photolysis, and the amounts of 1,3-dichlorohexafluoro propane formed were measured. In Fig. 2, the rate of formation of 1,3-dichlorohexafluoro propane is plotted against the amount of 1,2-dichlorotetrafluoro ethane added. It can be seen that substantial

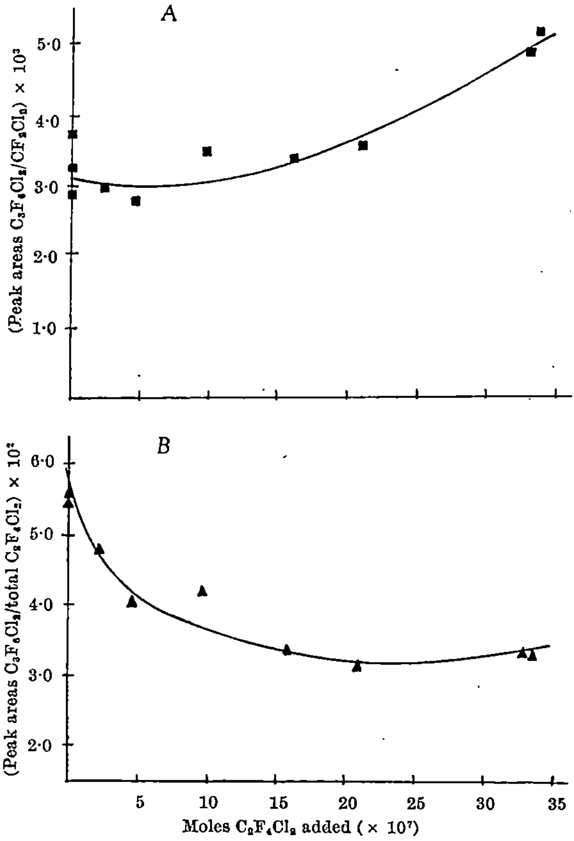

Fig. 2. *A*, yield of $C_3F_6Cl_2$ against moles $C_2F_4Cl_2$ added; *B*, ratio $C_3F_6Cl_2$ to $C_2F_4Cl_2$ produced + $C_2F_4Cl_2$ added against moles $C_2F_4Cl_2$ added

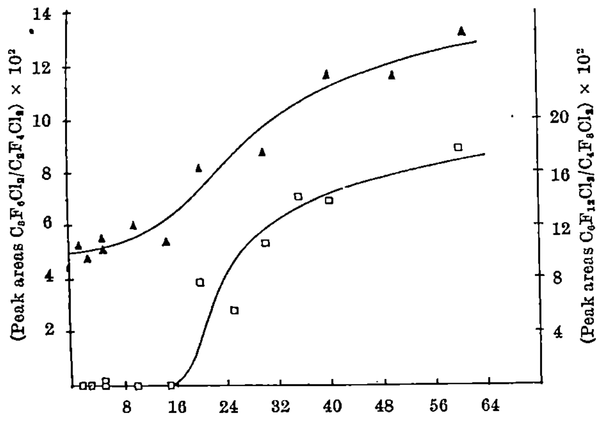

Fig. 3. Ratio of secondary to primary products against time. ▲, CF_2Cl_2 photolysis; □, $C_2F_4Cl_2$ photolysis

amounts must be added before any effect is perceptible, and these amounts are more than three times the concentration of 1,2-dichlorotetrafluoro ethane usually observed in the mercury photosensitized decomposition of CF_2Cl_2. In Fig. 2*B*, it is shown that the ratio of 1,3-dichlorohexafluoro propane to 1,2-dichlorotetrafluoro ethane actually decreases when extra amounts of 1,2-dichlorotetrafluoro ethane are added.

Finally, in Fig. 3, the ratios $[C_3F_6Cl_2]/[C_2F_4Cl_2]$ and $[C_6F_{12}Cl_2]/[C_4F_8Cl_2]$ are plotted against irradiation time, and it can be seen that the induction period, clearly visible for $C_6F_{12}Cl_2$ formation, is absent for $C_3F_6Cl_2$ formation.

It therefore appears probable that 1,3-dichlorohexafluoro propane, formed in the mercury photosensitized decomposition of CF_2Cl_2, arises by the interaction of primary radicals and does not involve a second excited mercury atom colliding with initially formed products. This does not rule out the possibility that CF_2 is formed in a single step:

$$Hg^* + CF_2Cl_2 \rightarrow CF_2 + HgCl_2$$

but this appears unlikely in view of the appearance of 1,3-dichlorohexafluoro propane in the photolysis products of 1,3-dichlorotetrafluoro acetone, where such a process cannot occur. Further, the ratio $[C_3F_6Cl_2]/[C_2F_4Cl_2]$ has the same value (0·04) in both systems.

Reaction of Tetrafluoroethylene with Pentacyanocobaltate Ions and with Reduced Vitamin B_{12}

We have previously shown[1] that a cobalt–carbon bond can be formed in aqueous solution by the interaction of acetylene with the pentacyanocobaltate(II) anion, while recently[2] benzyl and alkyl halides have been similarly shown to give a Co–C bond.

We have found that tetrafluoroethylene is readily absorbed at atmospheric pressure by aqueous solutions of the hydridopentacyano-cobaltate(III) ion, $[HCo(CN)_5]^{3-}$, as well as by the pentacyano-cobalt(II) ion. The well-crystallized salts analyse correctly for $K_3[(CN)_5CoCF_2CF_2H]$ (*A*) [for example, Found: C, 20·8; N, 17·4; F, 18·0; Co, 14·2; K, 29·1. Required: C, 20·6; N, 17·2; F, 18·7; Co, 14·5; K, 28·8 per cent] and $K_6[(CN)_5Co(CF_2)_2Co(CN)_5]\cdot 2H_2O$ (*B*); the salts are stable in air and thermally up to about 300° C.

The nuclear magnetic resonance spectra support these formulations. Thus the H^1 spectrum for (*A*) is a triple triplet while the fluorine-19 resonance of the β-CF_2 is split into a doublet by the proton and further into a triplet by the α-CF_2 group; all these lines are sharp and well resolved. In contrast the α-CF_2 resonance is a broad single line; the broadening is presumably due to incomplete averaging of the spin coupling with the cobalt-59 nucleus produced by quadrupole relaxation of this nucleus. For the same reason, the fluorine-19 spectrum of (*B*) is only a broad single line.

The interaction of C_2F_4 with the hydrido-species is interesting in that it can provide a probe for the detection of transition metal to hydrogen bonds in aqueous media where detection by the high-field proton resonance line is difficult. Thus we have failed to observe such a high-field line in saturated aqueous solutions of the grey-green reduction product of cyanocobalamin. A search was made at 40 Mc/s several years ago[3], at the time of our first investigations of the hydridic nature of lower oxidation states, and, more recently, at 56·45 Mc/s. However, the reduced species immediately absorbs tetrafluoroethylene, and the resulting red product—dissolved in chloroform–phenol, in which it is much more soluble than in water—shows a ^{19}F resonance spectrum in which there is a doublet of splitting similar to that observed for the —CF_2H group of (*A*). While this suggests that reduced cyanocobalamin (B_{12s}) is a hydrido-species, we cannot rigorously exclude the possibility that it is a cobalt(I) species as recently suggested[4], since such a cobalt(I) species could react with C_2F_4 with subsequent hydrogen transfer from the solvent.

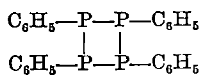
Molecular Structure of Phosphobenzene

The following polyphosphines of formula $(C_6H_5P)_n$ have been reported in the literature: (*A*) m.p. 149°–150° (refs. 1–9); (*B*) m.p. 190° (refs. 2 and 3); (*C*) m.p. 252°–256° (ref. 3); (*D*) m.p. 260°–285° (ref. 8). Compounds *C* and *D* are insoluble in organic solvents and have, presumably, a polymeric structure. The molecular weights of *A* and *B* in solution have not been established definitely. Several isopiestic, ebullioscopic and cryoscopic methods have been used by various workers and the following identities have been proposed. *A* = *B* = I[2]; *A* = I, *B* = II[3]; *A* = *B* = II[8]; *A* = II[4,5,9]. Recently it has also

$$C_6H_5-P=P-C_6H_5$$

I



$$\begin{array}{c} C_6H_5-P-P-C_6H_5 \\ |\quad\ \ | \\ C_6H_5-P-P-C_6H_5 \end{array}$$

II

been shown[8] that compounds *A* and *B* are tetraphenyl-*cyclo*-tetraphosphines (II) which differ in both the dissolved and solid states and are stereoconformers.

We have prepared compound *A* by the reaction of phenylphosphonous dichloride and phenyl phosphine[1,3-5] (equation 1):

$$nC_6H_5PCl_2 + nC_6H_5PH_2 \rightarrow (C_6H_5P)_n + 2nHCl \qquad (1)$$

and by a new method which involves the heating of phenylphosphine and a stoichiometric amount of phenylphosphonous bisdimethylamide at 170° for 1 h (equation 2); the yield is 83 per cent (ref. 10). This new method has also been used successfully for the preparation

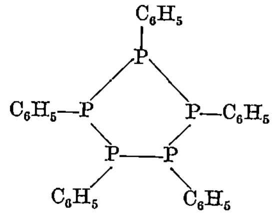
$$n\mathrm{C_6H_5P[N(CH_3)_2]_2} + n\mathrm{C_6H_5PH_2} \rightarrow (\mathrm{C_6H_5P})_n + 2n\mathrm{(CH_3)_2NH} \qquad (2)$$

of triphosphines (for example, 1,1,3,3,-tetraphenyl-2-methyltriphosphine m.p. 134°, equation 3) and biphosphines[11] (for example, tetramethylbiphosphine).

$$\mathrm{CH_3P[N(CH_3)_2]_2} + \mathrm{2HP(C_6H_5)_2} \rightarrow \mathrm{(C_6H_5)_2P{-}P(CH_3){-}P(_6H_5)_2} + \mathrm{2(CH_3)_2NH} \qquad (3)$$

The identity of the compound *A* prepared according to either equations 1 or 2 has been established by melting points, mixed melting points, infra-red spectra[12] and X-ray diffraction spectra. The molecular weight, determined cryoscopically in benzene, was found to be 439 ± 25; this corresponds to structure II, theoretical value 432·9: analysis $\mathrm{C_6H_5P}$ (108·07): calc., C, 66·67; H, 4·66; P, 28·66 per cent: found, C, 66·36; H, 4·65; P, 28·87 per cent.

Crystals of compound *A* (recrystallized from acetonitrile, m.p. of a single crystal 154°–156°), which has also been called phosphobenzene, are monoclinic, $P2_1/n$. The cell dimensions are a = 9·742, b = 10·139, c = 27·488 Å, β = 90·0°. The density, measured by flotation, is 1·324 g/c.c.; thus, assuming $Z = 4$, then M = 541. The calculated molecular weight for $\mathrm{(C_6H_5P)_5}$ is 540. In an attempt to throw some light on this discrepancy with solution measurements, an X-ray single crystal analysis has been carried out. The diffracted X-ray intensities were measured with the aid of a Hilger and Watts linear diffractometer; 2,614 of these intensities were assigned non-zero value, the remainder being ignored. The positions of the five phosphorous atoms in the asymmetric unit were obtained from a three-dimensional Patterson synthesis. From this point, the 860 observed planes with $\sin \vartheta/\lambda < 0{\cdot}35$ Å^{-1} were utilized in the calculations. The positions of the carbon atoms were determined from two successive three-dimensional electron density maps. Seven cycles of least-squares refinement reduced R from 0·35 to 0·10. The results show that, in the solid state, compound *A* is a pentamer, $\mathrm{(C_6H_5P)_5}$, with structure III.



III

We have now started to refine the structure with all 2,614 observed planes; the full results of the analysis will be published elsewhere.

Compound *B* was prepared according to the directions given in the literature[8]. From 4 identical preparations two yielded compound *B* exclusively whereas one preparation gave compound *B* in addition to a polymeric material melting at 215°–265°, and the other preparation gave compound *A* in addition to a material melting at 240°–275°.

A part from the crude compound *B*, m.p. 180°–185°, was recrystallized from benzene containing small amounts of acetonitrile. The compound was obtained in well-shaped crystals melting at 183°–186° in an open tube and at 229°–235° in an evacuated tube. The compound resolidified very slowly and then melted at 130°–155°. Analysis indicated that the compound contained one mole of benzene per 6 phenyl-phosphorus groups. The benzene could not be removed in the vacuum at room temperature; analysis $\mathrm{(C_6H_5P)_6.C_6H_6}$: calc., C, 69·42; H, 4·99; P, 25·58 per cent; found, C, 69·48; H, 5·09; P, 25·21 per cent.

Another part of crude *B*, recrystallized from tetrahydrofuran, was obtained in small needles melting at 189°–193° in an open tube and at 194°–198° in an evacuated tube.

Crystals of compound *B* recrystallized from benzene are rhombohedral, space group $R3$ or $R\bar{3}$. The cell dimensions are a = 10·12 Å, α = 77·574° or, when referred to hexagonal axes, a = 12·68, c = 20·96 Å. The density, measured by flotation, is 1·257 g/c.c.; thus, assuming $Z = 1$, the molecular weight is 737. The calculated molecular weight for $\mathrm{(C_6H_5P)_6.C_6H_6}$ is 726. The required molecular symmetry for $\mathrm{(C_6H_5P)_6}$ is 3 in the space group $R3$ or $\bar{3}$ in the space group $R\bar{3}$.

When recrystallized from tetrahydrofuran, crystals of compound *B* are monoclinic, space group $P2_1/c$. The cell dimensions are a = 12·31, b = 6·16, c = 24·86 Å, β = 117·64°. The symmetry of the $h0l$ reciprocal net is almost hexagonal, plane group p6m. The density, measured by flotation, is 1·275 g/c.c.; thus, assuming $Z = 2$, the molecular weight is 642. The calculated molecular weight for $\mathrm{(C_6H_5P)_6}$ is 649, and the required molecular symmetry for $\mathrm{(C_6H_5P)_6}$ is $\bar{1}$.

The cell dimensions are very similar to those found[13] for $\mathrm{(C_6H_5As)_6}$ which has a = 12·16, b = 6·22, c = 24·10 Å, β = 110·23°, space group $P2_1/c$.

Thus, although the possibility that compound *B* is a dimer or trimer cannot be excluded, it seems very probable that, in the solid state, it is a hexamer.

We thank Dr. H. H. Zeiss for his advice.

A New Polymorph of Oxamide

IN his investigations at high pressure, Bridgman[1] found evidence of four polymorphs of oxamide, but he did not identify them. Two forms of oxamide have been obtained in an exploration of methods of preparation of the compound; either form may be prepared from the other by recrystallization.

Oxamide that is stable at room temperature is triclinic, and this form was described by Ayerst and Duke[2]; it is prepared by the hydrolysis of cyanogen by concentrated hydrochloric acid[3] or by thermal dehydration of ammonium oxalate[4]. An orthorhombic form of oxamide that is metastable at room temperature was obtained when oxamide was prepared by glow-discharge electrolysis of formamide[5] or when oxamide was crystallized rapidly from its solution in formamide. Only the triclinic form was obtained at any cooling rate from a hot aqueous solution of either form. Crystallization from 1,4-dioxane, dimethyl formamide, glycerol, or ethylene glycol also yielded only the triclinic form.

The orthorhombic form is obtained by rapidly cooling from 70° C to room temperature a solution of either form of oxamide in formamide. If the solution is cooled slowly (5° C/h), the triclinic form is obtained; at intermediate cooling rates, orthorhombic seed crystals develop

epitaxial overgrowths of the triclinic form or develop into monocrystal pseudomorphs of the triclinic form. At temperatures below 0° C, however, only triclinic oxamide is obtained at any rate of cooling.

Triclinic oxamide crystals in a saturated formamide solution showed no alteration after 4 weeks at 25° or 40° C. Orthorhombic crystals in a saturated formamide solution at room temperature developed a grainy texture from the growth of triclinic crystallites on the surface. In a saturated aqueous solution at 25° or 40° C, mixtures of the two forms showed a gradual decrease in the proportion of the orthorhombic form. Orthorhombic crystals that were crystallized from formamide, washed with acetone, air-dried, and stored in stoppered containers altered similarly and slowly formed triclinic monocrystal or oriented polycrystalline pseudomorphs.

Orthorhombic oxamide crystallizes as bipyramids flattened along N_γ and elongated along N_α, but more frequently as bevelled plates resulting from greater growth distortions along N_α and N_γ. Plate crystals, which result from rapid crystallization, commonly show penetration twinning. There is a moderately good cleavage plane parallel to N_β–N_γ in the plates. The crystals have class *mmm* symmetry and extinction positions are either parallel or symmetrical on principal views, in accord with orthorhombic symmetry. Refractive indices are $N_\alpha = 1\cdot430$, $N_\beta = 1\cdot685$, $N_\gamma = 1\cdot695$. The crystals are biaxial (–) with small $2V$, as shown by diffuse conoscopic figures; calculated $2V$ is 20°.

The X-ray diffraction spectra of the two modifications, Table 1, have many reflexions in common, suggesting a close structural similarity. The infra-red spectra of the triclinic[6] and orthorhombic forms are identical. Attempts to determine the unit-cell parameters of the orthorhombic dimorph were unsuccessful, however, because untwinned crystals of this dimorph large enough for single-crystal investigation could not be prepared. Satisfactory Weissenberg photographs were not obtained from even the largest twinned crystals. Further attempts will be made to determine the space-group symmetry of the orthorhombic dimorph.

BIOPHYSICS

Use of Microwave Techniques for the Determination of Bound Water

ANY information about changes in the structure of molecular arrays which are reflected in changes of the water substance is useful to form a guideline for future work that tries to investigate the actual atomic and molecular basis of life. An accurate and relatively fast method has been developed which can assess the occurrence of a quantity called bound water. These bound-water molecules are defined by the fact that they are unable to follow the changing electric field of an applied microwave signal, indicating thereby that they are either bound to 3 or 4 other molecules of the same kind, or to various other types of molecules. The remaining water molecules (those bound to 2, 1 or no other water molecules) that are free to rotate with the impressed electromagnetic field absorb energy from the incident microwave signal. The difference between the two microwave signals can be interpreted to be an indication of the amount of water bound to a particular molecule.

Since water molecules have an appreciable dipole moment, they will tend to follow an applied electric field if not impeded by their environment. During this process of molecular re-alignment energy is expended and subtracted from the incident energy.

The sample, an aqueous solution of the substance to be investigated, is located at a certain point in a cavity the resonant frequency of which is in the microwave *X* band. In that frequency range most energy is absorbed by the water and only a negligible amount by the 'contaminating' substance. The response of the cavity to incoming microwave signals is then displayed as a function of their frequency on an oscilloscope or *X*–*Y* plotter and from that picture the dielectric constant of the sample material can be obtained. From the dielectric constant at microwave frequencies one may obtain in turn the static dielectric constant and plot that as a function of concentration of the solute. The initial slope of that graph then gives a quantity that is linearly related to the amount of water irrotationally bound to the solute molecules. Changes in that quantity can be recorded conveniently by photographing the oscilloscope trace (for fast changes) or by reduction of the response curve data to the desired quantity by means of an electronic computing device.

The rectangular cavity operates in the TE_{104} mode. The sample is contained in the glass tube which is located near a minimum of the electric field existing in the cavity. If one assumes that the change in the cavity characteristics due to the introduction of the sample is small, one may use the perturbation analysis developed by Slater[1] and applied to measurements of low loss dielectrics by Birnbaum and Franeau[2]. Our modifications change the expressions given by the latter authors to give the values of the dielectric constants in the form:

$$\Delta\varepsilon' = \varepsilon_w' - \varepsilon_s' = \frac{2c}{f_0}(f_s - f_w) \tag{1}$$

$$\Delta\varepsilon'' = \varepsilon_w'' - \varepsilon_s'' = C\left(\frac{1}{Q_s} - \frac{1}{Q_w}\right) \tag{2}$$

where $\Delta\varepsilon'$ or $\Delta\varepsilon''$ signifies the relative change in the dielectric constant of the material contained in the glass tube; the subscript (s) denotes properties pertaining to the solution and (w) to pure water. ($f_s - f_w$) is the shift in the resonant frequency of the cavity due to replacement of the pure water by an equal volume of solution, f_0 is the resonant frequency of the empty cavity, and C is a constant derived from cavity dimensions, given by:

$$C = V_0/4AV_T \tag{3}$$

where V_0 is the volume of the empty cavity, V_T the volume of the total dielectric material, and A is a correction factor for the position of the glass tube relative to $E_{\max}$.

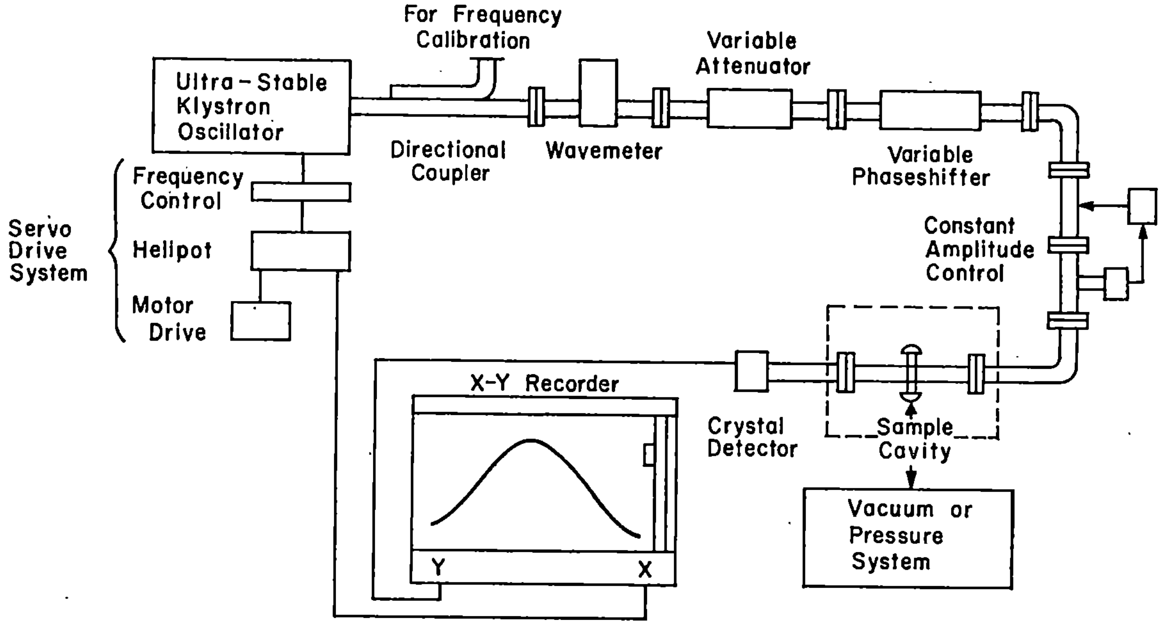

Fig. 1. Block diagram for dielectric constant measurement of aqueous solutions of microwave frequencies

The graph of ε_s, the static dielectric constant, as a function of concentration, is then used for further computations. The reason for the use of the static dielectric constant as an indicator of the amount of bound water can be explained by the following argument.

At the high electromagnetic frequencies used in the present method the protein or large solute molecule together with its shell of bound water may be considered as one unit, a cavity in the surrounding medium that has a relatively low dielectric constant; the bound water can only contribute to the static dielectric constant by virtue of its electronic and atomic polarization, which is small.

At low solute concentrations we assume with Haggis, Hasted, and Buchanan[3] that ε_s depends linearly on the concentration of solute so that:

$$\varepsilon_s = \varepsilon_{\text{water}} - \delta \cdot c \tag{4}$$

and:

$$\delta = \beta \frac{(\varepsilon_{\text{water}} - \varepsilon_{\infty\text{prot}})^{v} + (\varepsilon_{\text{water}} - \varepsilon_{\infty\text{water}})^{w}}{100} \tag{5}$$

where c is the concentration in g protein/100 ml. solution, v the partial specific volume of protein, $\varepsilon_{\infty\text{prot}}$ the high-frequency dielectric constant of protein, $\varepsilon_{\infty\text{water}}$ is the high-frequency dielectric constant of water, w is the weight of water irrotationally bound to 1 g of protein, and β is a parameter depending on the axial ratio of the spheroidal macromolecule.

Because of the uncertainty in estimates of some of the parameters in the foregoing equation, we only use the technique to measure relative changes in the water of hydration, either as a function of time during a given reaction, or as a function of concentration of some other substance that reacts with the given solute molecules.

Fig. 1 shows the schematic diagram of the experimental arrangement of the instruments. The Laboratory for Electronics Ultrastable X-band generator is used as a microwave source. The output is frequency-modulated by means of a potentiometer-monitored drive that produces a concurrent voltage signal to serve as the X signal on the X–Y plotter. Over the frequency range used (9·450–9·470 Gc/s) the output of the generator is amplitude-modulated to keep the intrinsic power variation of the klystron at less than 0·01 db. The amplitude modulation is accomplished by superimposing a lossy cavity characteristic and then taking a sample of the power, which is detected by a crystal, amplified, and fed back into a gyrator. A wavemeter, precision attenuator and phase-shifter precede the sample cavity and the detector crystal. The sample cavity is immersed in a constant temperature bath and the waveguide section containing it is kept at constant temperature and humidity by dried- and temperature-controlled air. Samples of solution are drawn into the cavity by gravity flow after the capillary section in the cavity is evacuated.

The foregoing outlined technique has been used[4] to determine changes in the water bound to hæmoglobin as xenon is introduced into the solution. Further experiments involving hæmoglobin, other proteins, and enzymes are in progress.

BIOCHEMISTRY

A Suggested Role of Amino-acids in Deoxyribonucleic Acid

Several investigators have found amino-acids among the hydrolysis products of DNA's from many sources and some have suggested that small peptides may play a part in DNA structure and/or function. These have been reviewed by Bendich and Rosenkranz[1]. We have considered the possibility that such small peptides are concerned with the regulation of enzyme synthesis. For this reason we have examined the amino-acid residues found in samples of DNA from *Escherichia coli* grown in 'minimal' and in 'complete' media. Bacteria grown in minimal media must synthesize large numbers of compounds not made by those grown in complete media. Therefore, more enzymes should be formed and more DNA should be functional in bacteria grown in minimal media. If control of DNA function is exerted through firmly bound amino-acids

Table 1. AMINO-ACID RESIDUES IN SEVERAL *E. coli* DNA's

(μg amino-acid residue/100 mg DNA)

* DNA was extracted from washed log phase *E. coli* B cells by the procedure of Kirby (ref. 2). An extra deproteinizing step was carried out just prior to dialysis. The DNA was dissolved in 10 per cent sodium chloride, deproteined twice with $CHCl_3$-i-AmOH, and reprecipitated with cold EtOH.

† DNA was extracted as described by Marmur (ref. 3). Samples of bacteria, 1–5, were kindly supplied by Dr. L. Kaplan, of this Institute. Samples 6 and 7 were purchased from General Biochemicals, Chagrin Falls, Ohio, and were in late log phase; all others were in mid-log.

No. 1: grown in an American Sterilized Co. Biogen, Davis (ref. 11) salt medium without citrate and 1 per cent glucose. Nos. 2 and 3: grown in Davis salt medium (ref. 11) and 1 per cent glucose in two independent batches. No. 4: grown in a biogen as No. 1 but with addition of 0·6 per cent yeast extract. No. 5: grown in 2·5 per cent Difco heart infusion broth. Nos. 6 and 7: batch grown with 4 per cent yeast extract, 2 per cent dextrose, 0·3 per cent KH_2PO_4, 0·1 per cent K_2HPO_4. No. 7 was treated with 50 mg/l. proflavine and irradiated with a 750-W lamp at 8 in. for 60 min. No. 6 was an untreated control for No. 7.

and peptides, then DNA from bacteria grown under these two sets of conditions should contain different amounts of amino-acids.

The bacteria were gathered and the DNA's were extracted by the use of either phenol[2] or sodium dodecylsulphate[3]. All samples were treated with RNase and then with chloroform and iso-amyl alcohol until no further protein was removed. The DNA's were characterized by the diphenylamine reaction[4] and by spectral shifts after treatment with DNase[5]. The DNA's were hydrolysed at 110° *in vacuo* with 6 *N* hydrochloric acid. The amino-acids were then determined with a Spinco Stein–Moore amino-acid analyser[6].

The results in Table 1 show that the total of the neutral and acidic amino-acid residues in the DNA from *E. coli* grown in minimal media ranged from about 8 to 12 hundred μg/100 mg DNA, while those from the bacteria grown in rich media were about 200 μg/100 mg DNA. The relative proportions of the individual amino-acids were about the same in each group. In one sample of each group, the basic amino-acids were determined. Essentially the same differences were observed as were seen with the neutral and acidic amino-acids. In one sample (No. 7), obtained from bacteria irradiated in the presence of proflavine, only 15 per cent of the DNA was extractable. In investigations with acridine orange, similar results were obtained by Smith[7], who postulated that the rest of the DNA was linked to protein. In view of the foregoing, it is interesting that this sample of DNA has the same amount of residual amino-acids as the unirradiated control (No. 6).

The possible significance of the bound amino-acids is emphasized by the finding that the same differences were observed in DNA samples prepared by the two quite different methods. Three different enriched and two minimal media were used. Despite these variations, the DNA from bacteria grown in minimal medium retained a much greater amount of bound amino-acids than the DNA from cells grown in enriched media. These differences support the suggestion that amino-acids may play a part in repression–derepression of enzyme synthesis, in addition to any structural function they may have[8].

If, as in the schemes of Jacob and Monod[9], a regulator gene in essence can act only to repress a structural gene (whether directly or indirectly), then blocking such action would lead to derepression. The data presented here are consistent with such a mechanism, that is, small peptides acting as rather firmly bound derepressors. (In this regard it is interesting to note that Gallant and Stapleton[10] have published data supporting the suggestion that repressors also are peptides.) Thus, we should expect bacteria grown in minimal medium to need many enzymes, and, therefore, their DNA to contain large amounts of derepressors. Such a mechanism of derepression might also explain control of enzyme function in differentiated tissue and in such dedifferentiated tissues as tumours.

We thank Dr. George B. Brown for his advice.

Inhibition of Glycolysis by Pyruvate in Relation to the Accumulation of Citric Acid Cycle Intermediates in the Perfused Rat Heart

RECENT investigations have established that the addition of metabolic fuels such as acetoacetate, fatty acids, lactate or pyruvate to hearts perfused with glucose and insulin inhibits the rate of glucose uptake and oxidation[1–4]. It has been proposed that during respiration of these substrates, glycolysis is inhibited by a common mechanism; namely, an indirect inhibition of phosphofructokinase as indicated by increased levels of hexose monophosphates and decreased levels of fructose-1,6-diphosphate[5]. Furthermore, phosphofructokinase activity has been shown to be depressed in hearts from diabetic rats which also have a decreased rate of glucose utilization[6]. It has recently been reported that citrate not only inhibits phosphofructokinase activity in cell-free system, but also accumulates in hearts from diabetic rats, and in isolated hearts perfused with long- and short-chain fatty acids[7–9]. These results have led to the suggestion that the rate of glycolysis may in some measure be controlled by the activity of the citric acid cycle. Williamson[10] has reported that the rate-limiting step of glycolysis in perfused hearts with pyruvate as substrate occurred not at the phosphofructokinase step, as proposed by Newsholme *et al.*[5], but at a site located between glyceraldehyde-3-phosphate and pyruvate. It was therefore considered of interest to examine the kinetics of the changes of the glycolytic intermediates after addition of pyruvate, in conjunction with the levels of certain citric acid cycle intermediates in both the intact heart and isolated heart mitochondria.

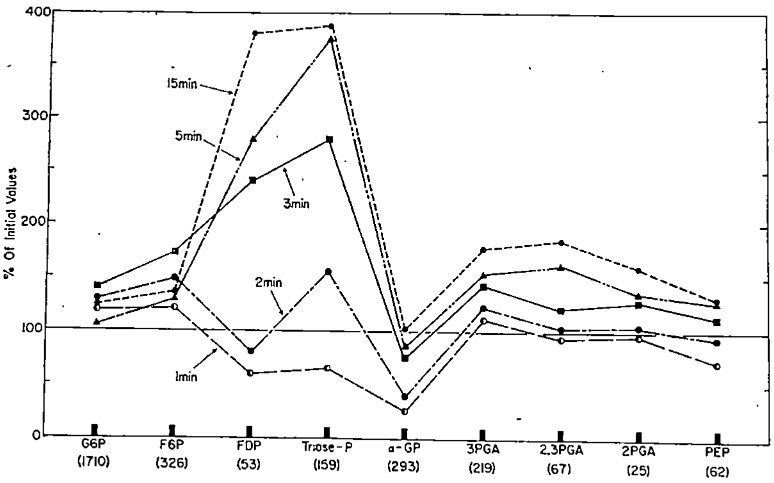

Fig. 1. The effect of pyruvate on the level of glycolytic intermediates in isolated, perfused rat heart. Hearts were perfused for the stated times with 5 mM glucose, 2 mU/ml. insulin, and 10 mM pyruvate. Control hearts were perfused with similar medium in the absence of pyruvate. Values for the glycolytic intermediates represent the mean of determinations on two hearts for each perfusion time, and results are expressed as a percentage of the initial control values. Control values for each intermediate are expressed in μmoles/kg dry wt. and are shown in brackets at the bottom of the figure. Dihydroxyacetone-P accounted for 83 per cent of the triose phosphate

Hearts from fed, male, Wistar rats were perfused as previously described[1]. All hearts were pre-perfused for 15 min with medium containing 5 mM glucose and 2 mU/ml. insulin before transference to recirculation circuits containing 15 ml. of the same medium plus 10 mM pyruvate. After different times of perfusion, the hearts were rapidly frozen by means of tongs cooled in liquid nitrogen, powdered, and extracted with perchloric acid. The glycolytic intermediates, citrate, α-oxoglutarate and malate, were estimated in an Eppendorf fluorimeter by minor modifications of standard enzymatic procedures[11]. Rat heart mitochondria were prepared and incubated as described by Chance and Hagihara[12]. The redox state of the mitochondrial pyridine nucleotides was investigated using the fluorescence techniques of Chance and Baltscheffsky[13].

The changes of the glycolytic intermediates in hearts at different times after exposure to pyruvate are shown in Fig. 1. It may be seen that glucose-6-phosphate and fructose-6-phosphate levels were elevated within 1 min after addition of pyruvate and remained elevated for the 15-min perfusion period. Fructose-1,6-diphosphate and triose-phosphate levels decreased within the first minute, but afterwards increased greatly above the control values, with fructose diphosphate lagging behind the triose phosphates. The intermediates between 3-phosphoglyceric acid and pyruvate also increased, but to a lesser extent than the triose-phosphates. The levels of α-glycero-P decreased by 75 per cent immediately after pyruvate addition and afterwards increased to the same values as those of the control hearts. The ratio of α-glycero-P to dihydroxyacetone-P decreased from an initial value of 2·2 to a plateau value of 0·5–0·6 2 min after the addition of pyruvate, indicating a change of the cytoplasmic pyridine nucleotides towards a more oxidized state.

The amounts of citrate, α-oxoglutarate and malate determined in the same experiment are shown in Fig. 2. All three compounds increased after 1 min, with citrate showing the most rapid initial increase, and after 15 min the values were, respectively, 15, 5 and 34 times the controls.

Experiments were performed with rat heart mitochondria to obtain information on the mechanism of citrate accumulation. With 5 mM pyruvate and 2 mM fumarate as substrate, the mitochondria respired rapidly and showed good respiratory control. On aerobic incubation with these substrates in the presence of phosphate acceptor, α-oxoglutarate, after a 1-min lag, was formed at the rate of 7·5 μmoles/g protein/min over a 12-min period. The initial level of α-oxoglutarate was 2 μmoles/g protein. The citrate content of the incubation medium remained constant at the initial value of 7 μmoles/g protein. Citrate also remained constant if the incubation with pyruvate and fumarate was carried out in the absence of phosphate acceptor. Addition of pyruvate (with or without fumarate) produced a rapid increase of reduced pyridine nucleotides, which was reversed by arsenite (an inhibitor of pyruvate oxidase) but not by malonate. Similar effects have been obtained with the intact beating heart[14], and NADH was found to be the major form of reduced pyridine nucleotide contributing to fluorescence increase, although NADPH also increased by 50 per cent.

The changes in the levels of the glycolytic intermediates after pyruvate addition illustrate the development of several different blocks along the glycolytic pathway. The addition of pyruvate is followed by an immediate rise of hexose monophosphates, citrate and α-oxoglutarate, and a fall of fructose-1,6-diphosphate and triose-phosphates. These changes are consistent with an initial inhibition of phosphofructokinase by citrate. The subsequent rise of triose-phosphates prior to fructose-1,6-diphosphate suggests the development of a more powerful inhibition at an enzymatic site between glyceraldehyde-3-P and 3-P-glyceric acid, even though citrate-levels continue to increase. However, the presence of a further block between 3-P-glyceric acid and pyruvate is indicated by the slow rise of the former intermediate immediately after pyruvate addition. The most feasible explanation for the observed changes of the glycolytic intermediates, therefore, involves primary inhibition of pyruvate kinase by the high concentration of pyruvate[15], and secondary inhibition of triose-P dehydrogenase by the build-up of its inhibitory product, 1,3-di-P-glyceric acid[16]. It is clear from these results that, under the special conditions of a high pyruvate concentration, phosphofructokinase is not the major rate-limiting enzyme of the glycolytic pathway and that there is no correlation between the citrate content of hearts and the levels of hexose mono- or di-phosphates. Some degree of inhibition of phosphofructokinase is indicated, however, by the increased levels of hexose monophosphates, and this could be mediated

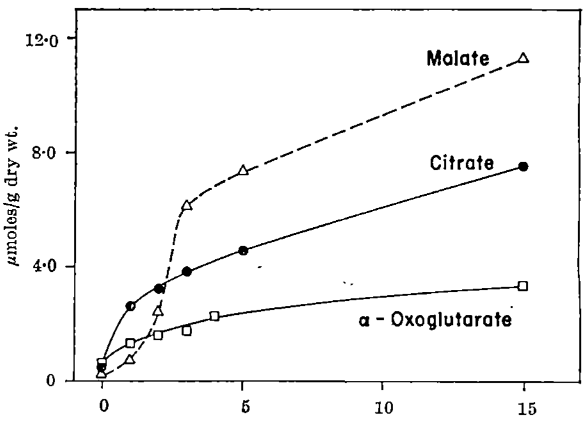

Fig. 2. The effect of pyruvate on the levels of malate, citrate and α-oxoglutarate in the isolated, perfused rat heart. The perfusion conditions were similar to those described for Fig. 1

by citrate. Possibly, initial inhibition of phosphofructokinase is reversed by the build-up of fructose-1,6-diphosphate, which has been shown to be a potent antagonist of citrate inhibition[9].

The lack of citrate formation in isolated mitochondria, despite its accumulation in the intact tissue, suggests the possibility that much of the citrate found in the intact tissue may be formed in the cytoplasm. This may be accomplished either by reversal of the isocitrate dehydrogenase reaction[17], or by the extramitochondrial condensation of oxaloacetate and acetyl coenzyme *A* (ref. 18). The increased formation of reduced pyridine nucleotides after pyruvate addition in both the intact heart and isolated mitochondria, and the reversal of this effect by arsenite, indicate that pyruvate is readily converted to acetyl coenzyme *A*, while the accumulation of α-oxoglutarate suggests that α-oxoglutarate oxidation may be limited by the availability of free coenzyme *A*. Isocitric dehydrogenase does not appear to be a rate-limiting enzyme under the conditions of these experiments.

Staphylococcal Teichoic Acid Antibody in the Sera of Patients with Burns

THE sera of patients suffering from extensive burns have been found by one of us (J. K.) to contain precipitating antibodies to components of *Staphylococcus aureus* extracts. The presence of the antibodies was demonstrated by immunodiffusion methods from about two weeks after the first isolation of *Staphylococci* from the burned area. The more discriminating technique of immunoelectrophoresis showed that one of these numerous staphylococcal cell-components migrated rapidly towards the anode (its mobility similar to that of a phenol red marker). We have called this rapidly migrating component 'fast anodic antigen' (FAA); the antibody to it has only occasionally been found in normal human sera by the usual immunodiffusion methods. FAA is not an exotoxin but corresponds to a component of the cell wall.

Extracts containing FAA could be prepared by boiling or by autoclaving cells and also by perchloric acid or formamide extraction of whole cells. This suggested that FAA was probably a polysaccharide. For most of the present work, however, aqueous extracts were obtained from staphylococci (Glaxo strain 663) broken up in a modified Hughes press and subjected to brief ultrasonic treatment.

An antibody similar to FAA had been observed in the sera of rabbits immunized with whole-killed staphylococcal cells by a lengthy procedure (2 × 0·25 ml., 2 × 0·5 ml., 19 × 1·0 ml. doses intraperitoneally at 3-day intervals, 20,000 × 10^6 cells per ml.) designed to produce antisera to somatic antigens. Such antisera often showed by immunodiffusion in agar and on cellulose acetate the presence of at least eight distinct antibodies against whole-cell extracts, but by immunoelectrophoresis the one fast anodic arc could be clearly distinguished.

During immunochemical investigations of various staphylococcal cell fractions, we had observed that, among the active fractions, teichoic acid appeared to have an electrophoretic mobility similar to that of FAA when run on paper in barbitone buffer at *p*H 8·6. The teichoic acid extraction procedure of Baddiley *et al.*[1] from highly purified cell walls was used, although with our strains longer extraction times with trichloracetic acid (1 week) were required. The teichoic acid was finally freeze-dried, its identity being checked by chromatographic examination of acid and alkali hydrolysates.

We could confirm the observations of other workers[2,3] that teichoic acid can react with a specific serum antibody. We found teichoic acid to precipitate with antibody in antiserum from rabbits hyperimmunized with whole-killed staphylococcal cells. In spite of repeated attempts, however, we have been unable to immunize rabbits with pure teichoic acid and have concluded that it is not itself immunogenic and should therefore be designated as a haptene. The fact that whole-killed *Staphylococci* cells elicit a teichoic acid antibody response in rabbits points to some kind of structural association, involving teichoic acid within the cell wall, either as a higher polymer of teichoic acid than can be extracted with trichloracetic acid or as part of a moiety in which teichoic acid functions as haptenic determinant groups. In all probability the complex between teichoic acid and mucopeptide would fall into the latter class.

After these observations, we could demonstrate that teichoic acid on immunoelectrophoresis against both our potent rabbit antiserum and human burn serum gave a fast arc, suggesting that teichoic acid is serologically similar to FAA (Fig. 1). A further experiment—a linking immunoelectrophoresis run—showed confluent arcs, establishing beyond all doubt the identity of FAA and teichoic acid (Fig. 2). To the best of our knowledge this is the first time that a precipitating antibody to teichoic acid has been reported in human serum. Its presence was not surprising, as burn slough is almost invariably found to be heavily infected with *Staphylococci*, as well as with other organisms[5].

Recently, Mudd *et al.* have produced evidence of the part played by teichoic acid in inhibiting phagocytosis of *Staphylococci*[6]. They showed that normal human sera absorbed with teichoic acid had a reduced power to promote phagocytosis, presumably owing to combination of the teichoic acid with phagocytosis-promoting antibody. A precipitating antibody to teichoic acid would fit this picture reasonably well; the teichoic acid antibody would combine with the teichoic acid from the *Staphylococci*, leaving the phagocytosis unimpaired.

Work is in progress at present to determine the part played by teichoic acid in conferring immunity by examining various pathological human sera for the presence of antibody to teichoic acid. We are also extending the work on serum from burned patients; but it seems likely from our experience so far that high levels of this antibody can be attained in laboratory animals only after numerous injections over a long period and in man in special circumstances, such as those existing in burned patients.

An Anomalous Effect of Ethionine on Ribonucleic Acid Synthesis

Besides giving rise to liver tumours[1], ethionine administration causes inhibition of protein synthesis[1,2] and also, in common with actinomycin D and puromycin, can reduce the extra synthesis of certain enzymes occurring in liver under the influence of 'inducing' agents[3]. Actinomycin D is known to suppress the synthesis of ribonucleic acid (RNA) possibly including 'messenger' RNA, *in vivo* or *in vitro*, and puromycin likewise suppresses RNA synthesis at least when administered to partially hepatectomized rats[4]. A fall in the incorporation of labelled precursors into RNA has been briefly reported to occur in liver after acute treatment with ethionine in large dosage[2,5], in accordance with the inhibiting effect on protein synthesis. Surprisingly, however, we have now encountered a converse effect on RNA synthesis in rats fed ethionine.

The rats were young male albinos, kept on a 20 per cent protein diet which, for the experimental rats, contained 0·25 per cent DL-ethionine (usually omitted on the day before killing). From the livers, excised after an overnight fast, there were prepared both a DNA-containing 'enzyme aggregate'[6] and, with the use of 2·2 M sucrose, highly purified nuclei[7]. Both types of preparation were assayed for the DNA-dependent RNA-nucleotidyl transferase ('RNA transcriptase', 'RNA polymerase'; Enzyme Commission 2.7.7.6)[6], with no addition of DNA but sometimes with addition of ammonium sulphate (to 0·4 M; cf. ref. 8).

In calculating *in vitro* results for the purpose of Fig. 1, activities were expressed on the basis of the actual amount of DNA in the sample assayed. For the controls, the mean values for μμmoles of ATP incorporated per mg DNA per min without (or with) ammonium sulphate were 2·9 (or 9·5) for enzyme aggregate and 13 (unchanged by ammonium sulphate) for purified nuclei; the values for UTP were similar. Whereas ethionine treatment has led in other laboratories to bile-duct proliferation and a rise in DNA/g liver, no such changes have now been found, the mean value for DNA being 1·75 mg/g both in control and in ethionine-fed rats. It may also be pointed out that for ethionine-fed rats the recovery of tissue DNA was similar to that in controls, both for enzyme aggregate (about 60 per cent) and for nuclei (about 40 per cent), and the total liver weight characteristically fell to 80 per cent of that in controls.

Both enzyme aggregate and nuclei, assayed in the absence of ammonium sulphate, showed a marked rise in activity in ethionine-fed rats, some rise being evident even with one day of feeding (Fig. 1). If ammonium sulphate were added to the enzyme aggregate system, and the comparison made with control preparations to

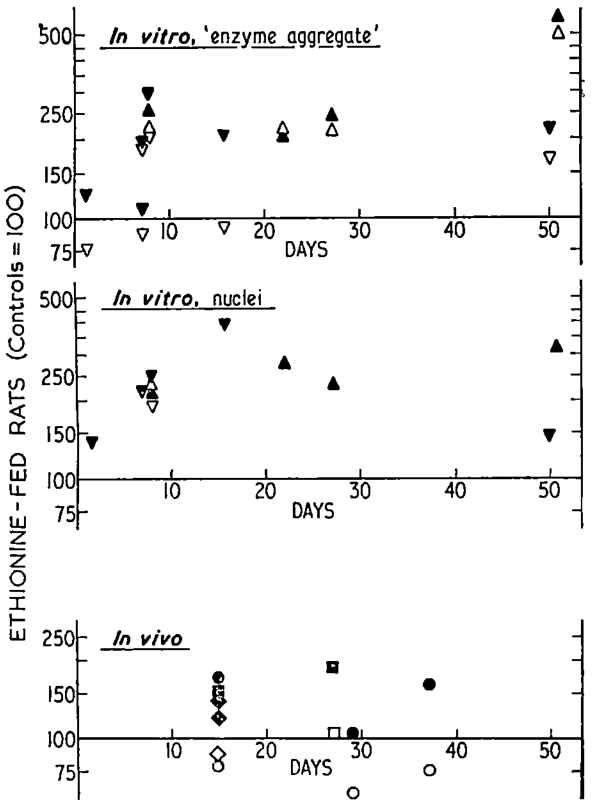

Fig. 1. RNA synthesis in rats fed ethionine (for the No. of days indicated on the axis), relative to that in controls (=100); see text for basis of calculation. Note log scale. *In vitro* results refer to the activity of RNA transcriptase, assayed on an 'enzyme aggregate' (top graph) or on purified nuclei (middle graph) as explained in the text. In one series of experiments (upright triangles) the precursor was ATP-8-^{14}C, and in a different series (inverted triangles) it was UTP-6-^{14}C. Assays without ammonium sulphate (solid triangles) and assays with ammonium sulphate added to 0·4 M (open triangles) were run side-by-side. *In vivo* results in the bottom graph refer to the recovery of radioactivity in whole-tissue RNA at different times after injection of orotate-6-^{14}C (solid symbols), and to the specific (not total) radioactivity of the uridine-nucleotide precursor pool (open symbols). Squares, circles and diamonds denote post-injection times of 30, 75 and 150 min respectively

which ammonium sulphate had likewise been added, the rise was reduced or abolished in some of the experiments with feeding periods of 16 days or less, but little reduced in most experiments (Fig. 1).

Measurements were also made of RNA labelling *in vivo* after injection of orotate-6-^{14}C (Fig. 1, bottom graph). With ethionine feeding the recovery of radioactivity in RNA was definitely enhanced, although less markedly than the incorporation *in vitro*. The enhanced recovery can validly be regarded as representing a rise in rate of RNA synthesis, since precursor measurements on the tissue suggested a fall rather than a rise in specific radioactivity (Fig. 1). Analyses on purified nuclei and on subfractions from the cytoplasm indicated that all cellular loci shared in the increase. Such analyses further showed that with ethionine feeding the amounts of RNA in purified nuclei and in the supernatant fraction were increased by up to 50 per cent.

There is, then, stimulation of RNA synthesis by feeding of ethionine, in contrast with the result obtained in acute experiments[2,5]. Preliminary experiments indicate that the stimulation found *in vitro* is not consistently, if at all, reduced by administration of actinomycin D or puromycin, but that (if account is taken of a tendency for precursor specific-activity to rise) the stimulation *in vivo* may be reduced by these agents or by adenine (the trial of which was prompted by its reported effect in reversing ethionine effects such as ATP depletion[1,2]). The tendency for the stimulation by ammonium sulphate to be reduced by ethionine, if fed for 16 days or less, suggests that there may be some increase in the availability of 'primer' DNA; but such a mechanism could evidently not account for the effect of ethionine when given for more than 16 days. Possibly the microsomal block in protein synthesis[2], while itself overcome with continued ethionine treatment[9], leads secondarily to a 'compensatory' increase in the output of messenger RNA, or else to a selective impairment of the formation of a 'repressor' governing the synthesis of RNA-synthesizing enzymes.

It should be emphasized that the qualitative agreement between the *in vitro* and the *in vivo* changes does not imply that RNA transcriptase is the sole enzymatic determinant of RNA synthesis. From the values for recovery of radioactivity in RNA *in vivo* and for precursor radioactivity, it would appear that the normal rate of RNA synthesis in liver is of the order of 3–8 mμmoles of UTP incorporated per mg DNA per min—a rate enormously greater than the *in vitro* rates already mentioned. Moreover, the turnover of RNA may also be governed by ribonuclease activity; in this connexion it is of interest that the acid–ribonuclease activity of supernatant fractions has been found in this laboratory to increase markedly in ethionine-fed rats.

In relation to the possibility that a rise in RNA synthesis is an important early step in heptocarcinogenesis, it should be pointed out that for carcinogenic azo dyes there is evidence of a rise in acute experiments[10], but with 2–5 weeks of feeding there is, in our experience, little change in RNA synthesis *in vivo* or *in vitro*. Moreover, there seems to be a striking rise in the rate of synthesis after prolonged feeding of α-naphthylisothiocyanate, which is non-carcinogenic but which (unlike ethionine as now given) causes bile-duct proliferation; but on addition of ammonium sulphate the activity *in vitro*, unlike that found after prolonged feeding of ethionine, becomes almost identical with that of controls likewise assayed in the presence of ammonium sulphate. In future work on the control of RNA synthesis, ethionine will evidently be a particularly useful tool.

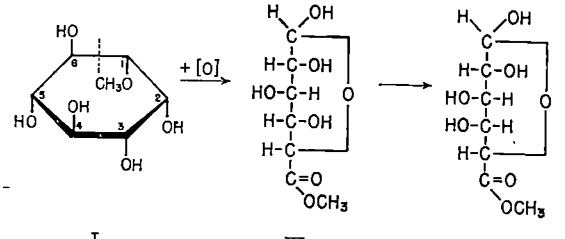
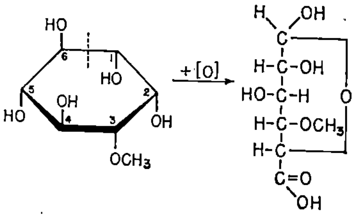
A Proposed Pathway for the Biosynthesis of Pectin and Methylated Uronic Acid Residues

MYOINOSITOL is readily converted into uronosyl and pentosyl monomers of pectin and related polysaccharides in higher plants[1,2]. During this conversion, myoinositol is cleaved between carbon atoms 1 and 6 and is oxidized at carbon 1 to yield D-glucuronic acid. The latter is further converted by the plant to a number of metabolic products including pectin and hemicellulose. It remains undetermined whether this conversion is an obligatory pathway of polysaccharide biosynthesis during cell wall formation, but certain theories may be advanced about the role of this process as a source of methylated uronosyl and pentosyl residues.

Four monomethyl ethers of myoinositol occur naturally[3]. They are L-bornesitol (1-*O*-methyl myoinositol) I, D-bornesitol (3-*O*-methyl myoinositol) II, D-ononitol (4-*O*-methyl myoinositol) III, and sequoyitol (5-*O*-methyl myoinositol) IV. (Hydrogen-carbon bonds are omitted in formulæ I, II, III, and IV.) If cleavage of the cyclitol ring occurs between carbon atoms 1 and 6 accompanied by oxidation of carbon 1 as observed in myoinositol, the product of 3-, 4-, or 5-*O*-methyl myoinositol will be 4-, 3-, or 2-*O*-methyl-D-glucuronic acid (V, VI, or VII).

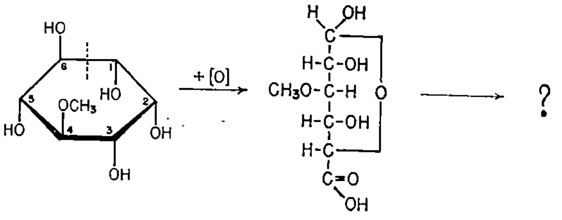


I IX X

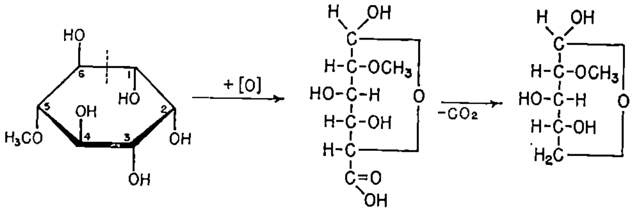


II V

4-*O*-Methyl-D-glucuronic acid is a common constituent of acidic polysaccharides found in hemicellulose[4], gums[5,6] and mucilages[6,7]. Characteristically, 4-*O*-methyl-D-glucuronosyl units occupy terminal, non-reducing positions, usually in short side-chains where they are attached to D-galactose or L-arabinose units or as single residues attached directly to the main chain of xylan. Presence of a 4-*O*-methyl group could control further chain enlargement and so have important consequences during polysaccharide biosynthesis[8]. Similarly, a 4-*O*-methyl group might also prevent decarboxylation[9] and so account for the widespread occurrence of 4-*O*-methyl-D-glucuronosyl units associated with pentosans. 3-*O*-Methyl-D-glucuronic acid has been reported in jute fibre hemicellulose[10]. No reports of naturally-occurring 2-*O*-methyl-D-glucuronic acid or its derivatives could be found although its decarboxylation product, 2-*O*-methyl-D-xylose VIII, has been isolated from plum leaf hemicellulose[11].



III VI



IV VII VIII

Now consider L-bornesitol. If this cyclitol is cleaved between carbon atoms 1 and 6 and carbon 1 oxidized, the product will be the methyl ester of D-glucuronic acid IX. This cleavage resembles an enzymatic reaction found in the microbial oxidation of camphor[12]. In the plant, the methyl D-glucuronate would have to be epimerized to methyl D-galacturonate *X* prior to its incorporation into pectin. Enzymatic steps that will catalyse this conversion as uronic acid nucleotides have been described[13], but the analogous conversion as methyl uronate nucleotides has not been explored. Incorporation of methyl D-galacturonate-U-^{14}C (methyl group unlabelled) into pectin has been demonstrated[14], but additional experiments are now needed to show that the methyl group accompanies uronic acid residues into polysaccharide during biosynthesis. Albersheim[15] has presented evidence that the rate of incorporation of myoinositol into pectin parallels the rate of incorporation of D-glucose and that in *Avena* coleoptile sections the effect of indolyl-3-acetic acid on incorporation of D-glucose and myoinositol into D-galacturonic acid residues and of methyl from methionine into methyl ester groups of pectin is similar.

The biosynthesis of myoinositol in plants proceeds from D-glucose without fragmentation of the carbon chain[16,17] by a cyclizing mechanism still not fully understood. Scholda, Billek, and Hoffmann-Ostenhof[18] have recently shown that myoinositol is the precursor of sequoyitol, D-inositol, and pinitol in leaves of *Trifolium incarnatum* infused with myoinositol-^{14}C. If so, it appears quite likely that L-bornesitol is also derived directly from D-glucose *via* myoinositol.

With considerations discussed here as a base, a hypothetical pathway of pectin biosynthesis is presented as follows:

D-glucose——→myoinositol——→L-bornesitol——→
methyl D-glucuronate——→methyl D-glucuronate
nucleotide——→methyl D-galacturonate nucleotide——→
pectin

Arrows between proposed intermediates do not necessarily indicate single step conversions. Indeed, in the plant all these conversions might well involve phosphorylated intermediates. The most important aspects of this new scheme are: (1) cyclization of hexose to a cyclitol; (2) methylation of the cyclitol; (3) oxidative cleavage of the cyclitol to the uronic acid methyl ester precursor of pectin, or the *O*-methyl glucuronic acid precursor of hemicellulose.

Time-dependent Inhibition of Myogenesis by Actinomycin *D*

MUSCLE owes its morphological and biochemical identity to proteins such as actin, myosin, tropomyosin, etc.,[1] and it is reasonable to suspect that these molecules are somehow represented in the genome. Until rather recently, it was generally believed that all new proteins are manufactured by freshly made messenger RNA's of exceedingly short half-lives. However, recently it has become rather evident that there are at least a few systems in which genetic messages are sent many generations before they are used[2]. Is this the case with myogenesis, or is the necessary information for muscle differentiation sent shortly before it is called into play?

Actinomycin *D* seemed to provide an experimental approach to the question. The antibiotic complexes with DNA and thereby prevents synthesis of RNA. At the same time, already-formed templates continue in the manufacture of proteins and DNA replication occurs[3]. The myogenic system selected for investigation was regenerating mouse skeletal muscle. This choice was dictated primarily by the fact that there is a great deal of synchrony attending the reaction: during the second to third day after muscle injury a class of highly proliferative mononucleated cells appears in the wound[4,5], and on the fourth day newly developing muscle fibres are in abundance. If the mononucleated cells are arrested by colchicine new muscle fibres fail to appear on schedule[5]. Moreover, if the mononucleated cells incorporate tritiated thymidine, differentiating muscle fibre nuclei show radioactivity after autoradiography[6,7]. Thus, it would seem that in the 3–4-day interval after wounding many presumptive muscle cells are achieving the differentiated state.

Transections were inflicted in tibialis anterior muscle of female Swiss-Webster mice, weighing 25–30 g, under light methoxyflurane anæsthesia. Animals received a single intraperitoneal dose of 0·99 micrograms of actinomycin *D* (kindly donated by Merck and Co.) at 24, 48, 72 or 100 h after transection. Tissues were fixed for histological investigation five days after wounding. Day five was chosen because at this time there normally are scores of regenerating fibres in each section through the wound[1–6].

Large numbers of typical five-day regenerating myotubes were encountered in all sections of the 24, 48 and 100 h series (Fig. 1). In five of five specimens given actinomycin at 72 h, regeneration was severely depressed (Fig. 2) and was represented by only an occasional, single, immature muscle fibre. Although few in numbers, these fibres were normal morphologically.

The findings indicate that myogenesis depends on a new round of RNA synthesis (presumably messenger) in the interval immediately preceding the histological advent of muscle as a tissue. This, in turn, suggests that muscle is specifically represented in the genome and that the information for making it is communicated shortly before it is used. Along this same line, it may be noted that muscle regeneration can be prevented by X-irradiation, but sensitivity to the effective dose is lost somewhere on the third day; that is, after the genetic messages seem to have been sent[8].

Occurrence of Homoserine in the Liver of Ethionine- or Methionine-treated Rats

INTRAPERITONEAL administration of L-methionine[1] as well as incorporation of DL-methionine[2] and DL-ethionine[3] in the purified diets of rats resulted in increased activity of rat liver cystathionase ('soluble' cysteine desulphydrase). Recently, I have also observed[4] that one injection of L-ethionine likewise caused, in 4 h, significant increase in the activity of the enzyme in rat liver. In an effort to determine the chemical basis for the effects of these amino-acids, analyses of the free amino-acids of the liver of control (non-treated) as well as of ethionine and methionine-treated rats were carried out.

For this purpose, male Wistar rats, weighing 90–100 g, were fed for 7 days a purified diet previously described[2], containing 18 per cent casein. The control animals were killed without any treatment; the ethionine- and methionine-treated animals were injected respectively with 54 mg L-ethionine and 48 mg L-methionine per 100 g body weight, by intraperitoneal route, 4 h before death. Another group was fed the purified diet containing 1·5 per cent DL-ethionine for a week. Free amino-acids were extracted from representative samples of 1 g of liver according to the procedure described by Awapara[5]. Chromatographic analyses of the extracts were performed on Whatman paper[4] (descending method), solvents: butanol/acetic acid/water (50:25:25) and phenol/water (80:20), on thin-layer silica gel (ascending method) using the same solvents, and in a Technicon autoanalyser after passing the extract through a column of 'Dowex 50', according to the method of Piez and Morris[6] as modified by Hamilton[7].

Presence of homoserine in the livers of ethionine or methionine-treated rats was indicated by paper chromatography and thin-layer silica gel chromatography. Furthermore, examination of the amino-acid profile obtained by the automatic recording apparatus revealed a peak in the position for homoserine, before that of glutamic acid, in the extracts of the ethionine- or methionine-treated rat livers. This peak was absent in the extracts of non-treated control animals' livers. Addition of DL-homoserine to the extract from control rat livers yielded a new peak located at the position identical with that occupied by the characteristic peak of the extracts from treated rats.

Demonstration of the accumulation of homoserine in the livers of ethionine- or methionine-treated rats is of particular importance, since administration of DL-homoserine itself[1], a substrate for cystathionase[8], induced an increase in rat liver cystathionase like methionine or ethionine. Matsuo and Greenberg[9] also reported the formation of radioactive homoserine in mice when injected with DL-methionine-2-C^{14}; however, the mechanism for the conversion of methionine to homoserine is not elucidated. According to Stekol *et al.*[10], methionine and ethionine follow the same metabolic pathway in the rat, but in the known pathway of the degradation of L-methionine[11], namely:

L-methionine → L-homocysteine → L-cystathionine → L-cysteine, the formation of homoserine could not be demonstrated, since the cleavage of L-cystathionine, the intermediate metabolite from which homoserine could be expected, gave rise only to α-ketobutyric acid and cysteine[6].

The elucidation of the mechanism of formation of homoserine in rat liver is under investigation.

Presence of Imidazoleacetic Acid Riboside and Ribotide in Rat Tissues

THE products of histamine metabolism *in vivo* have been catalogued in investigations of the urine[1,2], but relatively little work has been done on metabolites present in tissues. Since excreted metabolites reflect only the composite outflow of terminal products and need not represent the metabolites present in a tissue, it seemed of interest to examine the radioactive compounds present in some tissues after the injection of labelled histamine and histidine. A special effort was made to demonstrate the presence of histamine adenine dinucleotide (HAD) and histamine adenine dinucleotide phosphate (HADP)[3,4].

Male rats (300–350 g) were injected intraperitoneally with (2-^{14}C)histamine (18 μc./μmole) or uniformly labelled (^{14}C)-L-histidine (240 μc./μmole) and decapitated after specified intervals. Organs were homogenized in 5 per cent trichloroacetic acid (TCA), centrifuged, and the supernatant solution extracted with ether. Each of the aqueous extracts was added to a 'Dow 1-Cl⁻' column and eluted with water (fraction 1-I), 0·001 N hydrochloric acid (fraction 1-II), 0·0025 N hydrochloric acid (fraction 1-III) and 4 N hydrochloric acid (fraction 1-IV). Fraction 1-III was then chromatographed on 'Dow 50-H⁺' and eluted with increasing concentrations of hydrochloric acid. Aliquots of various fractions were chromatographed on Whatman 3 *MM* paper in ascending systems containing ethanol–0·1 N acetic acid (50 : 50) and isopropanol–0·5 N hydrochloric acid (65 : 35) and descending in isopropanol–chloroform–ammonium hydroxide–water (55 : 25 : 10 : 10). These solvent systems separate the known metabolites of histamine, although some uncertainty exists in differentiating between methylated and non-methylated compounds.

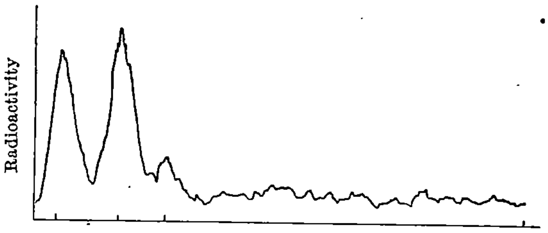

Fig. 1. Radioactive scan of chromatogram of TCA extract of kidney. The solvent system was isopropanol–CHCl$_3$–NH$_3$–H$_2$O

Histamine riboside, imidazoleacetic acid riboside, and imidazoleacetic acid ribotide were gifts of Drs. H. Tabor, H. Bauer and G. M. Crowley; histamine adenine dinucleotide phosphate (HADP) was a gift of Dr. S. G. A. Alivisatos. Labelled histamine adenine dinucleotide (HAD) and HADP were synthesized[3,4] with a pig brain DPNase[5].

Since kidney had the highest concentrations of radioactivity from injected histamine (Table 1), primary attention was given to that organ. Three major radioactive fractions were present on paper chromatography of the TCA extract (Fig. 1 and Table 2) of kidney from rats, each of which received a total of 35 μc. histamine (650 μg/kg) in three equal injections 120, 75 and 30 min before decapitation. On chromatography of the TCA extract on a 'Dow 1-Cl⁻' column, material that corresponded in all solvent systems with the radioactive peak at R_F 0·13 of Fig. 1 was eluted in fraction 1-I (Table 2), and radioactivity that chromatographed in all solvent systems as the peak at the origin of Fig. 1 was eluted in fraction 1-III (Table 2). All the radioactivity was eluted with water on chromatography of fraction 1-III on 'Dow 50-H⁺' (Table 2). The R_F values of the radioactivity in the chromatograms of these eluates corresponded with known imidazoleacetic acid riboside (fraction 1-I) and ribotide (fraction 1-III, 50-I) (Table 2). This identification was supported by hydrolysis of both 'Dow 1' eluates in 6 N hydrochloric acid for 64 h at 150° (ref. 6): chromatography of the hydrolysates showed that the radioactivity migrated in all systems with hydrolysed imidazoleacetic acid ribotide and with authentic imidazoleacetic acid. The third major peak in the chromatogram of the TCA extract (Fig. 1) did not correspond with any known metabolite tested (Table 2); hydrolysis of this material after elution from the chromatogram did not alter its R_F on chromatography. Similar chromatographic techniques showed the presence of imidazoleacetic acid ribotide in liver.

Since little radioactivity could be found in brain after the administration of labelled histamine (Table 1), it was necessary to inject labelled histidine to attain workable

Table 1. CONCENTRATION OF RADIOACTIVITY IN RAT TISSUES AFTER INJECTION OF LABELLED HISTAMINE AND HISTIDINE

levels of radioactivity. After the injection of 10 μc. of histidine both 120 and 30 min before decapitation (total histidine: 30 μg/kg), at least 80 per cent of the radioactivity migrated as histidine on chromatography of the TCA extract of brain. After chromatography on 'Dow 1-Cl⁻', eluate 1-I contained a small fraction of the total radioactivity that chromatographed in all solvent systems as imidazoleacetic acid riboside (Table 2) and which on hydrolysis with hydrochloric acid at 150° gave a product that migrated as imidazoleacetic acid. In addition, paper chromatography of fraction 1-III showed a radioactive peak corresponding to imidazoleacetic acid ribotide in all solvent systems (Table 2). The radioactivity incorporated into both the riboside and ribotide was less than 1 per cent of that in the total TCA extract, and of the same order of magnitude as the radioactivity identified as histamine and as imidazoleacetic acid. The radioactivity in these compounds was a function of the time between injection and decapitation and of the amount of isotope administered. Thus, when 30 μc. of histidine (45 μg histidine/kg) was injected into rats 120 min before decapitation, more than 5 per cent of the total radioactivity in the TCA extract was identified as imidazoleacetic acid ribotide on paper chromatography of fraction 1-III.

No evidence for the incorporation of radioactivity into HAD or HADP (histamine analogues of the nicotinamide adenine nucleotides) could be found after injection of labelled histamine or histidine into rats or guinea pigs 30 or 120 min before decapitation. To escape detection, less than 0·02 per cent of the total radioactivity in rat kidney or liver and less than 0·3 per cent in the rat brain (from histidine) could represent HAD or HADP. The dinucleotides may turn over too rapidly to be detected by these methods[7].

Although these experiments are only roughly quantitative and were not designed to measure steady-state levels in tissues, it is clear that tissue metabolites differ from urinary metabolites[2], which are imidazoleacetic acid riboside, 60–70 per cent; methylimidazoleacetic acid, 5 per cent; imidazoleacetic acid, 2 per cent; and acetylhistamine, 4 per cent. These results were obtained after a dose of histamine of 10 mg/kg, considerably higher than that used in the work recorded here. In kidney, multiple injections of histamine resulted in about half the label appearing in imidazoleacetic acid riboside with nearly as much in imidazoleacetic acid ribotide, not previously reported as a metabolite *in vivo*, and a smaller fraction in a third spot not coinciding with any of the urinary metabolites. In brain, after injection of labelled histidine, chromatographic data indicated the presence of imidazoleacetic acid riboside and ribotide, representing small fractions of the total tissue radioactivity, together with histamine, imidazoleacetic acid, and higher levels of unidentified metabolites.

The most likely pathway for synthesis of the ribotide is through condensation of imidazoleacetic acid with phosphoribosyl pyrophosphate a reaction demonstrated *in vitro*[8,9]; the riboside would then arise by dephosphorylation[9].

PHYSIOLOGY

Acetylcholine Receptors in Muscle Membrane

Cæsium depolarization of muscle membrane is further increased when choline is added to the bathing cæsium-Ringer solution[1,2]. This cæsium-choline depolarization remains constant in the continued presence of cæsium, even when choline is removed from the Ringer. When cæsium is replaced by potassium following removal of choline, the cæsium–choline effect is reversed and the normal resting membrane potential is recovered[2]. It appears that choline reacts in specific fashion with membrane 'receptors', the result of this reaction depending on cæsium and potassium ions; in the presence of cæsium, a depolarization results; in the presence of potassium, none. Scanning data show that when muscles are treated with cæsium–Ringer, the entire muscle surface becomes sensitive to choline. The work presented here was designed to elucidate the action of acetylcholine (ACh) on the cæsium-treated muscle membrane, in comparison with the action of choline (Ch) previously described, and to determine whether: (1) an additional depolarization is evoked only when cæsium is added before acetylcholine; (2) D-tubocurarine and eserine have any effect on the additional depolarization produced by ACh.

The experimental work was carried out under conditions identical to those previously described[1,2]. Eighteen pairs of sartorius muscles from *Rana pipiens* were used in each experimental solution. Each point in the figures is the average of potential measurements on 170 cells. The *S.E.M.* for membrane potential measurements is less than 1 mV. Bathing solutions were made up by adding cæsium, potassium, choline, acetylcholine, eserine or

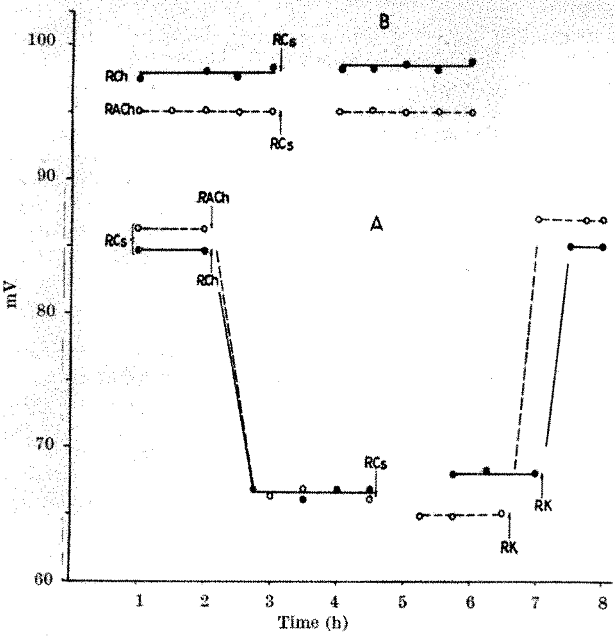

Fig. 1. Frog sartorius muscle membrane potential versus time after dissection. Bathing solutions indicated as follows: *R*.Cs = 2·5 mM cæsium–Ringer; *R*.Ch = 10 mM choline–Ringer; *R*.ACh = 10 mM acetylcholine–Ringer; *R*.K = normal (2·5 mM K) Ringer

D-tubocurarine in appropriate amounts to standard potassium-free Ringer (112 mM NaCl, 1·89 mM $CaCl_2$, 2·5 mM Na_2HPO_4, 0·5 mM NaH_2PO_4). Experiments with eserine were carried out in bicarbonate buffer. All experiments were performed at 25° C. The effects on the resting membrane potential of the various treatments are summarized in Figs. 1–3.

Fig. 1*A* indicates that 10 mM ACh or Ch evokes an additional depolarization in muscle fibres previously soaked in cæsium–Ringer. This additional depolarization is not reversed when muscles are washed with cæsium–Ringer free of Ch or ACh, but is reversed after washing with normal (2·5 mM potassium) Ringer. Equivalent amounts of either ACh or Ch evoke the same fractional depolarization, approximately 1·3 for 10 mM ACh or Ch. Neither substance produces this fractional depolarization in the absence of cæsium, or in normal Ringer (Fig. 1*B*). Addition of cæsium to cæsium-free Ringer containing ACh or Ch does not evoke the additional depolarization (Fig. 1*B*); the cæsium–choline or cæsium–acetylcholine effect is only observed when muscles are first equilibrated with cæsium.

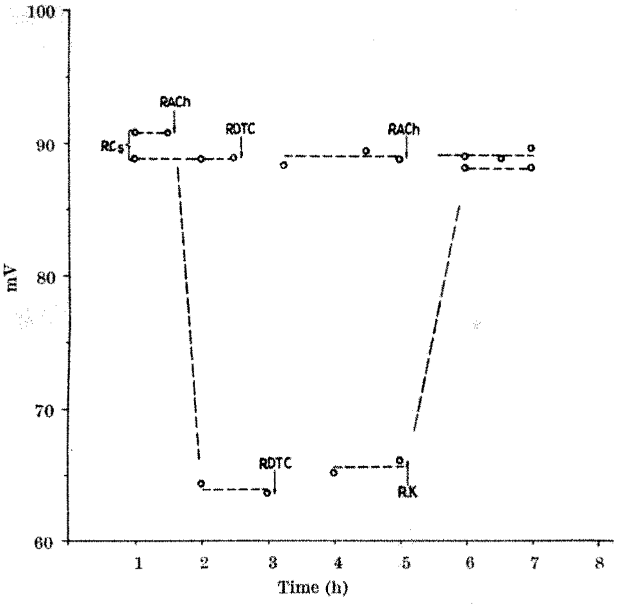

Fig. 2. Same as Fig. 1; *R*.DTC = D-tubocurarine–Cs–Ringer (1·4 × 10^{-4} M)

Fig. 2 shows that addition of D-tubocurarine to muscles previously soaked in cæsium–Ringer blocks the depolarizing effect of ACh or Ch added later. The depolarization produced by ACh or Ch added before D-tubocurarine is not altered when the muscles are afterwards washed with D-tubocurarine–cæsium–Ringer, but it is reversed when they are washed with normal Ringer, just as in Fig. 1*A*.

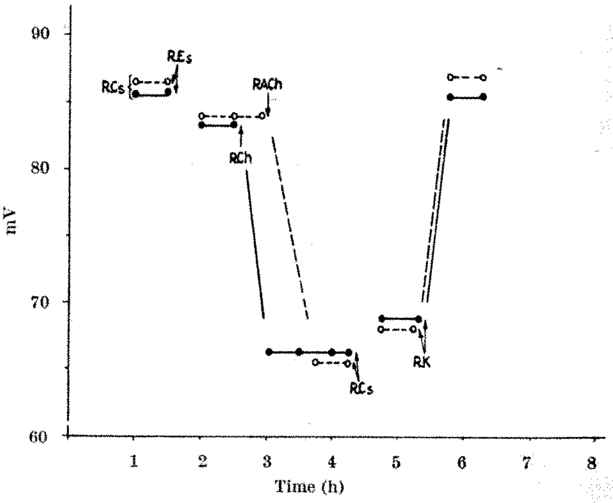

Fig. 3. Same as Fig. 1; *R*.Es = eserine–Cs–Ringer (1 × 10^{-3} M)

Fig. 3 demonstrates that the cholinesterase inhibitor, eserine, has no effect on the cæsium–ACh or cæsium–Ch depolarization, nor on its reversal by normal Ringer.

Results of scanning investigations under each of these experimental conditions showed no statistically significant regional differences in the average resting potential throughout the entire muscle cell surface, including end-plate regions[2].

The results obtained indicate that the stable depolarizing effect of Ch or ACh is only evoked when the membrane receptors are first 'sensitized' by cæsium ions. Cæsium does not sensitize these receptors if they have already been occupied by Ch or ACh. Evidence has been obtained that these receptors are located in the external surface of the muscle membrane[2]. Recent work has demonstrated that ACh reacts only at the external surface of the motor end-plate membrane of muscles fibre soaked in normal (2·5 mM K) Ringer[3]. The whole Ch–cæsium or ACh–cæsium-receptor complex is needed to produce the observed depolarization. It also appears that cæsium and potassium ions evoke different configurations in the receptor system, and consequently change its molecular complementarity to ACh or Ch in a different way. The restoration of the normal resting membrane potential by washing with normal Ringer after cæsium–ACh or cæsium–Ch depolarization suggests that potassium either releases ACh or Ch bound to receptors, or it restores the original configuration of the ACh- and Ch-receptor complex. (Experiments are in progress to determine differences in the rate of release of ^{14}C-labelled choline from muscles bathed in cæsium or potassium Ringer.) It has also been shown that the additional depolarization produced by ACh or Ch in cæsium–Ringer bears no relation to the external sodium ion concentration down to approximately one-third of the normal 112 mM sodium[1,4]. A direct and specific exchange between sodium and either Ch or ACh therefore seems most unlikely, as does the hypothesis that the depolarization is due only to a specific increase in sodium permeability.

D-Tubocurarine presumably prevented Ch or ACh from reacting with the cæsium-sensitized receptors, and consequently blocked their depolarizing effects. On the other hand, inactivation of acetylcholinesterase by eserine did not significantly affect the Ch or ACh depolarizations. This suggests that cholinesterase is not directly involved in these effects. It also suggests, but does not establish, that cæsium may inhibit cholinesterase under these experimental conditions.

Taken together, the D-tubocurarine and eserine effects, and the reversal of depolarization by washing with normal Ringer, lead us to conclude that Ch and ACh react similarly with cæsium-sensitized receptors, and that the depolarization resulting from this reaction does not require esterase activity for its reversal. D-Tubocurarine combines with the receptors in a way which prevents ACh or Ch from reacting, regardless of the presence of cæsium, but cannot displace ACh or Ch from prior combination with the receptors. ACh and Ch appear to react with the receptors in normal Ringer, but no depolarization results, and the receptor reaction with cæsium is blocked. On the other hand, the depolarizing effect of the ACh- and Ch-receptor reaction after receptor sensitization by cæsium is reversed by removing the cæsium. All these results together suggest very strongly an allosteric type of effect[7]; if one region or site on the receptor molecule reacts with ACh, Ch and D-tubocurarine, and another region or site reacts with cæsium and potassium, and if a change at either site changes the reactivity of the other, our results can easily be explained. Work in progress is aimed at testing this hypothesis.

The absence of any detectable localization of the cæsium–Ch and cæsium–ACh depolarization indicates that these receptors must be distributed over the entire muscle cell surface, not restricted to the motor end-plate region. It is well established that in the absence of cæsium, externally applied D-tubocurarine blocks ACh depolarization at the only place it occurs, the motor end-plate[3]. Our results suggest that receptors similar to those normally active in the motor end-plate are in fact present all over the surface, but are kept in a configuration which does not allow ACh-receptor reaction to lead to depolarization. The data presented lend new support to the view of the presence of the ACh system in conducting fibres[5,6]. This configuration is changed by the effect of cæsium so that depolarization does result from the ACh reaction. The nature of the substance(s) or mechanisms by which the ACh-receptors outside the motor end-plate regions are normally maintained in a configuration not permitting depolarization remains to be elucidated.

Evidence for Sorption as a Mechanism of the Olfactory Analysis of Vapours

THE physiological basis for olfactory discrimination may involve at least two basic mechanisms which need not be mutually exclusive : (*a*) the receptors themselves may be more or less selectively sensitive to different groups of chemicals ; (*b*) the receptor sheet as a whole might separate chemical vapours by adsorption or absorption in a manner analogous to gas chromatography columns. There has been some supporting evidence for the first mechanism[1,2], and suggestive evidence for the second has recently been reported[3]. The evidence suggesting the second mechanism depends, in part, on sampling the activity from different regions of the frog olfactory mucosa by recording the discharges from two olfactory nerve branches (a lateral one and a medial one), which under a dissecting microscope appear to subserve different mucosal regions. That these branches do indeed subserve different mucosal regions is supported by recent electrical stimulation experiments. The antidromically conducted discharges in response to individual stimulation of the lateral and medial nerve branches were recorded by an electrode placed at several points on the epithelium. The discharge tracts for the two branches were quite separate and localized (Fig. 1).

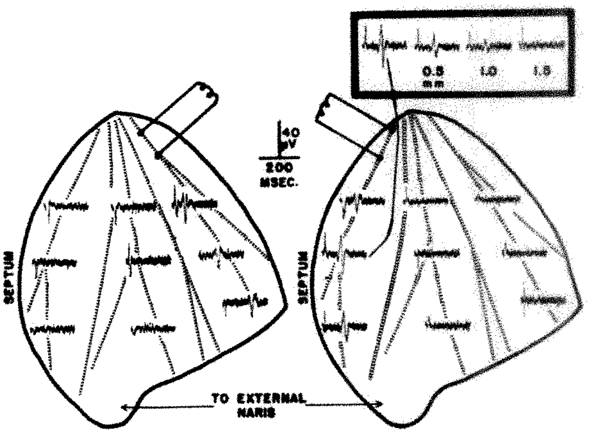

Fig. 1. Schematic diagram of the olfactory epithelium on the dorsal aspect of the olfactory sac of *Rana catesbeiana* showing the responses recorded at nine loci when the lateral nerve branch is stimulated (left) and when the medial nerve branch is stimulated (right). Hatched lines represent major olfactory nerve branches. The insert shows the reduction in response when the recording electrode is moved by 0·5 mm steps from the locus designated. Width of mucosa at the widest point is about 8 mm. Electrodes: bipolar, stainless-steel, 68μ diameter enamelled wire. Stimulator: Grass *S*4 with *SIU*4*A* isolation unit set for constant suprathreshold stimuli. This experiment was repeated in three animals with no appreciable difference in the results

I have observed[3] that the ratio computed by dividing the amplitude of the summated discharge recorded from the lateral nerve branch by that recorded from the medial nerve branch differed for different stimuli. In addition, the time lapse between the lateral nerve response and the medial nerve response (the latency difference) differed for different stimuli. These data demonstrated a space-time neural encoding of the analysis of the incoming vapours by the mucosa. In addition, since the latency differences could not easily be explained by selectively sensitive receptors, it was suggested that sorption along the mucosal sheet might also be involved in the stimulus analysis. Evidence to be reported here further supports this suggestion. This depends on the supposition that if sorption along the mucosal sheet played no part in the analysis and if selectively sensitive reactors were the only operative mechanism, the response amplitudes of the two nerve branches for any given chemical would not be appreciably changed in relation to each other by changing the direction of air flow through the nasal passageway. This would still hold even if the receptors were regionally grouped according to their selective sensitivity. If, on the other hand, the spatial separation of vapours by sorption were an important part of the analysis, the neural discharge pattern for any given stimulus would be considerably dependent on the direction of flow just as the region of greatest concentration at any given time in a physical sorption column is dependent on the point of entry of the gas.

These alternatives were tested by comparing the discharge magnitude of the lateral nerve branch to that of the medial nerve branch for several chemical stimuli under two conditions : (*a*) puffing the odorant into the external naris of the frog ; (*b*) puffing the odorant into the internal naris of the frog. The recording techniques, stimulating techniques, and data treatment have been described previously[3].

In all animals external naris stimulation with citral and geraniol yielded considerably larger responses on the medial nerve branch than on the lateral nerve branch, whereas internal naris stimulation with citral and geraniol yielded considerably larger responses on the lateral nerve branch and smaller responses or none at all on the medial nerve branch (Fig. 2). The shifts in response to *d*-limonene and octane were quantitatively much less but still in the same direction, although octane did occasionally show a slight shift in the opposite direction like that shown in Fig. 2. Thus, for citral, geraniol, and, to a lesser extent, *d*-limonene, the neural discharge patterns do indeed depend on the direction of air flow through the olfactory sac. Therefore, there is strong indication that sorption along the mucosal sheet is involved in the olfactory analysis of vapours.

It was also observed that internal naris stimulation yielded a shorter latency on the lateral nerve and a longer latency on the medial nerve than external naris stimulation, but this probably merely reflects the proximity of the mucosal regions supplied by these branches to each naris. However, no matter which branch responded first, when the chemicals were ranked according to the magnitude of the latency differences between their evoked responses on the two nerves, they fell into the same order regardless of the direction of air flow. This is not inconsistent with mucosal sheet sorption since the velocity of molecular movement through the olfactory passageway for each stimulus should not be expected to change with the direction of air flow *per se*.

It should be noted that because of vapour pressure differences, the stimulation with air bubbled through citral and geraniol was at a lower concentration than that with air bubbled through *d*-limonene and octane. Therefore the sorption mechanism and the resultant differential neural discharge may be analysing and encoding stimulus intensity rather than stimulus quality. This possibility is now being investigated.

HÆMATOLOGY

Slow Alpha$_2$-Globulin of Rat Serum

By immunological techniques, Darcy[1] has shown, in rats bearing a Walker's tumour, the appearance of a serum protein absent in normal rat serum.

Recently, several authors have demonstrated by starch-gel electrophoresis the appearance under certain conditions of a slow α_2-globulin in rat serum. This slow α_2-globulin has been found during certain periods of physiological activity : neo-natal period, gestation[2,3] and in animals submitted to various experimental conditions such as tumoral growth, surgical exeresis[2,4,5].

We tried to get some information concerning the biological significance of this protein by studying the variations of the level of the slow α_2-globulin during different states of normal growth, tissue regeneration and tumoral proliferation.

So, the level of rat slow α_2-globulin seems to reflect physiological and pathological growth processes. On the other hand, several authors have shown an increase of the hepatic mitotic index during different kinds of growth processes[6–8].

Since the liver seems to play the most important part in the synthesis of serum proteins, we thought that it might be interesting to compare the appearance of slow α_2-globulin with the variations of the hepatic mitotic index.

Two different strains of ascitic hepatoma have been examined in rats—*C* and *D* zajdela hepatoma (Institut du Radium)[9,10]. Sera and ascitic fluids of these rats have very high levels of slow α_2-globulin on the 7th day after grafting of the tumour.

In starch-gel electrophoresis[11] using continuous as well as discontinuous buffer system[12], slow α_2-globulin moves as a narrow band which has a more cathodic position than α_1-*M* (ref. 13) of rat serum (Fig. 1). This α_1-macroglobulin has a sedimentation rate of 18·3 *S* and it is found in the first fraction during filtration on 'Sephadex *G* 200'[14,15]. By repeated freezing and thawing as well as by ageing this protein

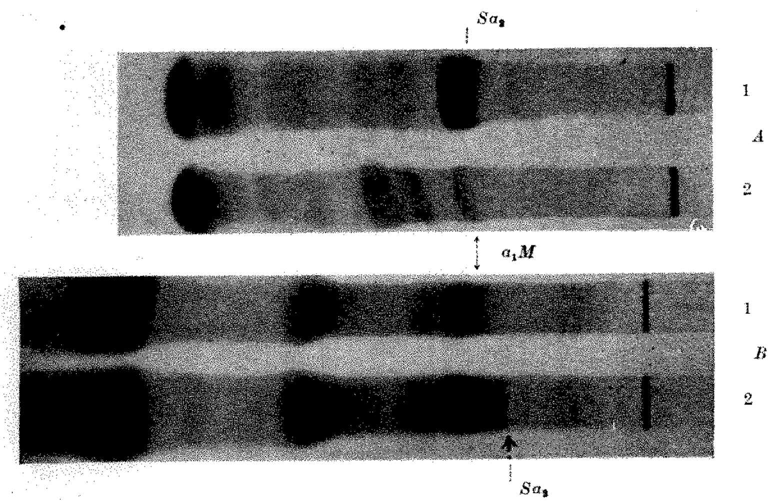

Fig. 1. Starch-gel electrophoresis, naphthalene black staining. *A*, discontinuous buffer system: (1) serum of hepatoma-bearing rat; (2) normal rat serum. *B*, Borate buffer: (1) normal rat serum; (2) serum of hepatoma-bearing rat

undergoes transformation in two constituents as revealed by starch-gel electrophoresis. The same behaviour was observed with the slow α_2-globulin. However, antigenic determinants of the two proteins under consideration are different.

Slow α_2-globulin is absent from normal rat serum as revealed by starch-gel electrophoresis. Furthermore, normal rat serum submitted to immunoelectrophoresis[16] using a specific rabbit anti-rat slow α_2-globulin serum[17] shows no trace of this protein. However, we always found this protein in the sera of rats bearing zajdela hepatoma (*C* and *D* strains) as well as in the sera of hepatectomized rats performed by the technique of Higgins and Anderson[18], as after nephrectomy or after laparotomy. Finally, we identified slow α_2-globulin in new-born rats during fifteen days after birth. The identity of slow α_2-globulin observed during the neo-natal period with the protein observed in the various experimental conditions described here has been proved by double diffusion testing.

The growth of young rats is quite regular during the first forty days of life and their body weight is generally doubled in intervals of nine days (Fig. 2). Liver weight increases following the same rhythm. The hepatic mitotic index of animals aged from one week to one month has been evaluated to 1·5–2 parts per thousand. This experimental work has been done on 5μ liver slices fixed in neutral, salted formol, included in paraffin and coloured by hæmatin–eosin–saffranin.

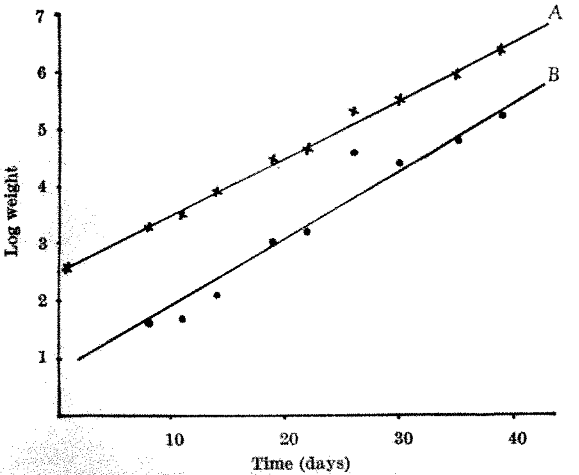

Fig. 2. Comparative diagrams showing the evolution of body weight and liver growth in rats. *A*, body weight of animals (g); *B*, liver weight (dg)

After the first month of life, the hepatic mitotic index decreases progressively until it reaches 0·05 parts per thousand in the adult animal. Slow α_2-globulin is present at a high level at birth time; it is then decreasing progressively and this protein is no more detectable under our experimental conditions around the fifteenth day of post-natal period.

Partial hepatectomy has been carried out in rats aged 6–10 weeks. A few hours later the cells of the remaining hepatic fragment show nuclear swelling and hypertrophy of the nucleoli. This is followed by a marked increase of mitosis. The mitotic reaction starts earlier in animals hepatectomized after six weeks of life (12–24 h) than in rats already ten weeks old (24–48 h). The highest level (10–15 parts per thousand) is reached after about 48 h. It returns to normal 7–10 days after hepatectomy. So far as slow α_2-globulin is concerned, it can be detected about 12 h after hepatectomy in animals 6 weeks of age and after 24 h in animals 10 weeks old. The titre of the slow α_2-globulin is highest after about 48 h; it then decreases and this protein is no longer detectable 10 days after hepatectomy.

The serum of rats hepatectomized three days after the grafting of ascitic hepatoma shows a very high level of slow α_2-globulin.

If unilateral nephrectomy is performed in rats 10 weeks old, the weight of the remaining kidney increases by about 60 per cent 10 days later. Practically no mitosis is seen in the removed kidney. Only a few mitoses are seen in the hypertrophic remaining kidney. However, slow α_2-globulin is present about 12 h after the removal of one kidney, but its level remains rather low. Hepatic mitotic index in these animals increases weakly to about 0·16 parts per thousand.

Simple laparotomy gives rise to the transient appearance of slow α_2-globulin between the 24th and the 48th hours.

Slow α_2-globulin appearing in rat serum during various states of physiological and induced growth, as well as after transplantation of ascitic hepatoma, has proved to be identical by immunological methods. So it became sure that this protein is not exclusively related to tumoral processes.

The existence of a very small quantity of slow α_2-globulin in adult male rats cannot be excluded. Indeed, we observed that certain sera of apparently healthy animals may absorb rabbit anti-slow α_2-globulin serum.

The results of our experiments do not corroborate the theory of direct interrelationship between hepatic mitotic index and the rate of synthesis of slow α_2-globulin. Indeed, the slow α_2-globulin appears before the elevation of the mitosis rate in hepatectomized animals. This protein is present after laparotomy and after nephrectomy in spite of a low mitotic index (0·16 parts per thousand). Slow α_2-globulin is absent in rats one month old whereas these animals show a ten-fold increase of the hepatic mitotic index as compared with the preceding cases. Although this protein is found during pregnancy, tumoral proliferation as well as during tissue regeneration and in the post-natal period, it is not in direct connexion with general tissue growth processes. Indeed, the evolution of slow α_2-globulin is not proportional to the variations of the hepatic mitotic index.

The real physiological meaning of the slow α_2-globulin remains unknown. Work is in progress, based on the use of fluorescent antibodies, to localize the cellular site of protein production.

Inhibition of Thrombin and of Fibrin Polymerization, Two Activities derived from Plasmin-digested Fibrinogen

As was previously shown in our laboratory[1], the clotting of fibrinogen initiated by one proteolytic enzyme (thrombin) is specifically inhibited by the products resulting from the action of another proteolytic enzyme (plasmin) on the same substrate.

Although this phenomenon has aroused considerable interest, the exact mechanism of the inhibitory action of these fibrinogen degradation products is still the subject of controversy. Some results indicated that fibrinogen degradation products affect mainly the first enzymatic step of the fibrinogen–fibrin conversion[2–4], another showed their predominant influence on polymerization–gelation steps of this conversion[5]. Recently, evidence has been presented that fibrinogen degradation products act solely as an inhibitor of the polymerization–gelation phase leading to the formation of a defective fibrin clot[6–8].

The results of the experiments described here indicate that in the course of plasmin-catalysed fibrinogen proteolysis at least two distinctly different activities can be found among a variety of degradation products.

The effect on the overall fibrinogen–fibrin conversion of fibrinogen degradation products formed at various times of fibrinogen digestion with plasmin is shown in Fig. 1. As can be seen from this graph, the prolongation of the thrombin time in the presence of fibrinogen degradation products reaches a maximum and then decreases to a constant level. A sharp decrease of the peak of the inhibitory activity to a constant level indicates that at least two active fragments may be derived from fibrinogen, activity of the first ('early' products) being, in contradistinction to the second ('late' products), destroyed by plasmin. It is not possible, however, to say now whether the second active fragment is the degradation product of the first or whether it is formed independently. Moreover, it should be pointed out that the activity of 'late' product(s) remains on a constant level, although the proteolytic reaction still proceeds.

Table 1. INFLUENCE OF 'EARLY' AND 'LATE' FIBRINOGEN DEGRADATION PRODUCTS (FDP) ON THE CLOTTING TIME OF FIBRIN MONOMER (*A*) AND FIBRINOGEN WITH THROMBIN (*B*)

	Clotting time (sec)	
	A	*B*
With saline	5	10
With 'early' FDP	20	80
With 'late' FDP	38	40

0·1 ml. (1·4 mg) of fibrinogen or fibrin monomer solution (both in 1 M sodium bromide *p*H 5·3) was mixed with 0·05 ml. of saline or FDP (0·25 mg) and immediately afterwards clotted by the addition of 0·7 ml. of 0·05 M phosphate buffer *p*H 7·6 to (*A*) or the same buffer containing 2·5 units of thrombin to (*B*).

Table 2. AMOUNT OF TCA-SOLUBLE PEPTIDES RELEASED FROM FIBRINOGEN, FDP, OR MIXTURES OF BOTH INCUBATED FOR 5 MIN AT *p*H = 7·8 WITH 0·024 N.I.H. UNITS OF THROMBIN

After addition of TCA up to 7·5 per cent final concentration, peptides in the supernatant were determined according to Lowry *et al.* (ref. 11)

Reaction mixture (4 ml.)	TCA soluble peptides in μg
(1) Fibrinogen (16·0 mg)	17·2
(2) 'Early' FDP (16·0 mg)	8·0
(3) Fibrinogen (16 mg) + 'early' FDP (0·8 mg)	14·7
(4) Fibrinogen (4·0 mg)	6·3
(5) Fibrinogen (4·0 mg) + 'early' FDP (0·8 mg)	4·3

It should also be noted that the difference in the effect of 'early' and 'late' fibrinogen degradation products on the thrombin time disappears at *p*H below 7. This problem will be discussed elsewhere[9].

Since the assay of the thrombin time does not enable us to decide which step of the fibrinogen–fibrin conversion is affected by fibrinogen degradation products, the comparison between the clotting time of a thrombin–fibrinogen mixture and fibrin monomer was made. The latter system makes it possible to measure the polymerization–gelation step alone, excluding the first enzymatic step. The results shown in Table 1 indicate that the 'late' fibrinogen degradation products affect the clotting time of both systems to the same degree. By contrast, a very distinct prolongation of the clotting time by the 'early' fibrinogen degradation products is observed in the system containing the thrombin–fibrinogen mixture, while the polymer-

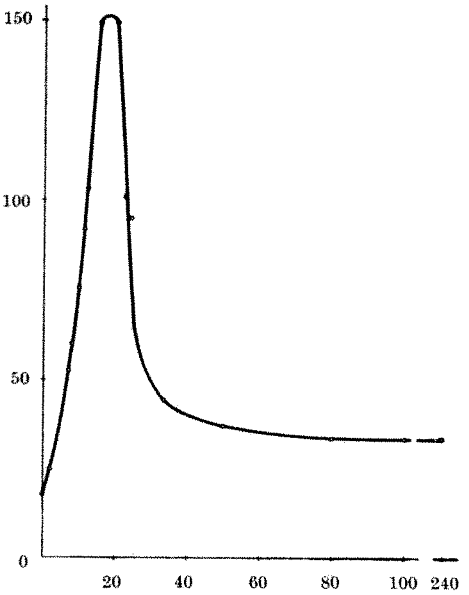

Fig. 1. Clotting time of fibrinogen by thrombin, in the presence of FDP formed in the course of fibrinogen proteolysis by plasmin. Bovine fibrinogen (96 per cent clottable) was incubated with human plasmin (90 cas. units/mg protein), the ratio being 100 : 3 respectively. The reaction was carried out at 37° C in *p*H-stat and *p*H = 7·8 was maintained with 0·1 N NaOH. To stop further action of plasmin, soybean trypsin inhibitor was added to the samples of the incubation mixture withdrawn at various time intervals. 0·5 mg of fibrinogen was mixed with 0·3 mg of FDP and clotted with 1 N.I.H. unit of thrombin at *p*H 7·6. Abscissa, time of fibrinogen digestion by plasmin (min); ordinate, clotting time (sec)

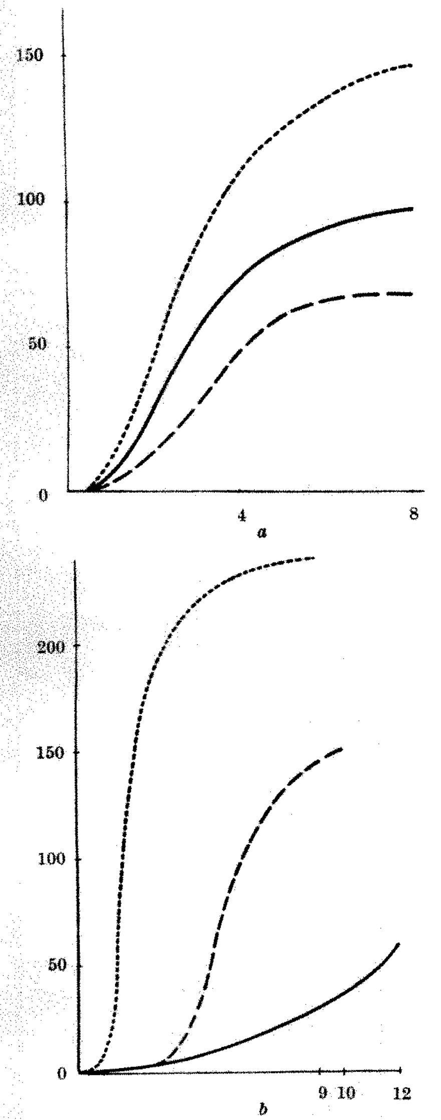

Fig. 2. Influence of 'early' and 'late' FDP on optical density changes during clotting of fibrin monomer (*a*) and fibrinogen with thrombin (*b*). Ordinates give absorbance at 350 mμ and abscissæ time (min). Final concentrations of fibrin monomer and fibrinogen were 0·45 mg/ml. and 0·55 mg/ml. respectively; concentrations of both 'early' and 'late' FDP were 0·12 mg/ml. Reaction *p*H = 7·5, phosphate buffer molarity 0·05; temperature 20° C. For experiments with fibrinogen 0·02 N.I.H. u./ml. of thrombin was used. Readings were performed every 15 sec. Upper dotted line—control (without FDP), solid line—with 'early' FDP, and broken line—with 'late' FDP

ization–gelation step, as tested by fibrin monomer clotting time, is much less affected.

In the experiment presented in Fig. 2 the effect of fibrinogen degradation products on both systems was followed by the previously described spectrophotometric assay[10]. The results presented in Fig. 2 are compatible with those of the experiments shown in Table 1. As can be seen from Fig. 2*a*, 'early' fibrinogen degradation products exert a much smaller inhibitory effect on fibrin monomer polymerization than 'late' fibrinogen degradation products. By contrast, when the overall reaction including the enzymatic step is followed by means of optical density recording, the reverse phenomenon is observed (Fig. 2*b*). This implies that 'early' fibrinogen degradation products affect mainly the first enzymatic step of the fibrinogen–fibrin conversion, whereas 'late' fibrinogen degradation products act as inhibitors of the polymerization–gelation step. Additional evidence for antithrombin activity of 'early' fibrinogen degradation products is provided by the assay of the amount of TCA-soluble peptides released by thrombin from fibrinogen in the presence of these products. The results displayed in Table 2 indicate that thrombin splits off less peptide material from the mixture of 'early' fibrinogen degradation products with fibrinogen as compared with the equivalent amount of fibrinogen alone.

All this indicates that among a variety of fragments released from the fibrinogen molecule after plasmin digestion two definitely different activities can be distinguished. One of them contained in 'early' products interferes with the enzymatic step of the fibrinogen–fibrin conversion and is plasmin susceptible. The other activity bound with 'late' products is plasmin resistant and interferes with the polymerization of fibrin monomer. It is not known whether the observed inhibition of the polymerization–gelation step by the 'early' fibrinogen degradation products is due to the action of the 'early' fibrinogen degradation products themselves or to the presence of the concurrently formed 'late' fibrinogen degradation products. Nevertheless, the originally proposed term 'antithrombin VI'[12] seems to be appropriate for the 'early' fibrinogen degradation products activity, whereas the term inhibitor of fibrin polymerization should be reserved for the 'late' fibrinogen degradation products activity.

The significance of the biologically active products of plasmin-catalysed fibrinogen degradation in the pathogenesis of acute fibrinolytic stages has been well recognized. Recently, the appearance of a severe hæmorrhagic diathesis in such cases has been ascribed mainly to the action of fibrin polymerization inhibitor(s) derived from fibrinogen[6,7]. The evidence displayed here suggests, however, that antithrombin activity of 'early' fibrinogen degradation products may, in fact, play an equally important part in the development of this coagulation defect.

Lack of Anti-A Hæmagglutinin Response to Influenza Infection

McDonald and Zuckerman have reported[1] an excess of blood group O and a corresponding deficiency of group A among patients with influenza A_2 infection. Blood group A-like antigens have been found in commercial influenza vaccines[2], and injection of non-dialysable material from such vaccines has given 4- to 15-fold increases in anti-A titres[3].

It is not known whether influenza virus *per se* contains A-like antigens capable of affecting the isoagglutinins; the reported increase in anti-A might be due to stimulation by antigens acquired from the chicken eggs in which the virus is grown. Investigations of the isoagglutinins during

Table 1. Isoagglutinin Changes during Influenza Infection

Table 2. Distribution of ABO Blood Groups

		A	O	B	AB	Total
Influenza A_2	Observed	105	93	15	8	221
	Expected	106	88	18	9	221
Influenza *B*	Observed	28	37	7	2	74
	Expected	36	30	6	2	74

influenza infection might therefore shed light on the antigenic content of this virus.

We have followed the isoagglutinin titres in paired sera collected from 221 patients with influenza A_2 and 74 patients with influenza *B* during 1961–64. The diagnostic criteria have been clinical symptoms accompanied by a 4-fold or greater increase in influenza antibody titres (complement fixation and/or hæmagglutination inhibition tests).

Our observations are summarized in Tables 1 and 2. Sixteen paired sera showing two or more titre-step difference from first to second sample have been retitrated. By this check only 3 showed the same difference, namely a 4-fold decrease in anti-A in one case and 4-fold decreases in anti-B in two cases.

It seems therefore justified to conclude that influenza infection does not produce any change in isoagglutinin titres.

The distribution of ABO blood groups among our patients with influenza A_2 corresponds to that of a normal control population, whereas the number of influenza B patients is too small for definite conclusions.

PATHOLOGY

Effects of Adenine and Guanine on Hepatic Glucose Release and on the Action of Insulin on the Liver

We have recently obtained information from work on normal subjects and mild and severe diabetics indicating that insulin has an increasing effect on hepatic glucose metabolism in untreated diabetics with progressively elevated fasting blood sugar-levels and glycosuria implying greater degrees of catabolism and gluconeogenesis[1]. There is also evidence of a hepatic action of insulin when diabetic patients are treated with phenethylbiguanide[2]. In view of the similarity between the ethylbiguanide side-chain and the nucleotides adenine and guanine, we wished to test the effect of these compounds on hepatic carbohydrate metabolism and on the action of insulin on the liver.

Using the rat liver perfusion technique developed by one of us[3,4], the release of glucose over two successive periods of 1 h has been investigated. Control levels were measured during perfusions with glucose-free tyrode solution and the effects of added adenine (in two concentrations, designated as Adenine, 0·25 γ/ml., or adenine, 0·025 γ/ml.), guanine (designated as Guanine, 0·25 γ/ml., or guanine, 0·025 γ/ml.) alone or with insulin (in two concentrations designated as Insulin, 20 milliunits/ml., or insulin, 0·2 milliunits/ml.) on hepatic glucose release expressed in mg/h have been examined so far.

Table 1

Perfusion	No. of expts.	Hepatic glucose release (mean ± *S.D.*) 1st h	Hepatic glucose release (mean ± *S.D.*) 2nd h
Control	12	4·7 (1·2)	4·7 (2·9)
Insulin	8	3·7 (1·0)	3·0 (1·2)
adenine	8	5·5 (1·8)	5·1 (2·1)
Adenine	10	10·4 (2·7)	8·3 (4·0)
Adenine + Insulin	8	8·3 (1·8)	2·5 (1·1)
Adenine + insulin	8	3·6 (1·2)	3·9 (1·6)
guanine	8	4·4 (2·7)	2·7 (1·8)
Guanine	10	8·3 (1·7)	8·3 (2·0)
guanine + Insulin	8	4·2 (2·6)	1·7 (0·9)
Guanine + insulin	8	4·6 (2·5)	3·1 (2·3)

The nucleotides guanine and adenine caused statistically significant increases in hepatic glucose release. Insulin, in concentrations which in previous work[3] failed to reveal a statistically significant action in controlled circumstances, suppressed the glucose-releasing action of the nucleotides, even at the lower dose-levels, suggesting that its action is hormonal rather than stoichiometric.

The results (Table 1) appear to be in close harmony with, and provide some degree of explanation for, the clinical findings here. If we consider the state of affairs in the fasting untreated diabetic, increasing demands for gluconeogenesis to offset losses through glycosuria will be associated with increasing protein catabolism. It seems probable that the concentrations of nucleotides, no longer involved in protein synthesis, might increase in the tissues, diffuse into the blood stream and perfuse the liver as well as accumulating locally from the cells in that organ. From the present evidence, it would appear that in low concentrations nucleotides may increase hepatic glucose release and that, in such circumstances, insulin, in levels which approach the physiological for the portal circulation, has a powerful action restraining hepatic glucose release.

Further work on the role of these phenomena on glucose homeostasis is being carried out.

Preparation of Antigens Specific of Human Breast Carcinoma by an Immunochromatographic Method

In spite of a rapidly mounting literature on the problem of specific antigens in human neoplasms, there have been few attempts to separate these antigens in amounts permitting biochemical and immunological analyses of the same. Such analyses not only would shed light on carcinogenic mechanisms, including possibly the serological back-tracking of eventual biological agents, but would make possible a much-desired immunological classification of tumours. Work from this laboratory has been concentrated on such efforts.

In previous reports we have described methods to extract potential antigenic proteins from human tissues, both normal and neoplastic[1-3]. Even though immunodiffusion and direct cytotoxicity tests have indicated amply the existence of specific precipitinogens and cytotoxinogens in neoplastic cells, the antibodies hitherto produced on a large scale in large animals were not always totally devoid of activity against normal antigens from normal cells.

The production of large amounts of hyperimmune γ-globulins required the use of large animals and hence the need for increasing amounts of antigens. These requirements automatically limited the possibilities of inoculating separate animals with separate tumours and compelled us to work with large pools of different tumours and of normal tissues.

Departing now from antibodies produced against pooled tumour antigens and pooled normal tissue antigens, we investigated a more homogeneous pool consisting of 4 adenocarcinomas of the breast.

As reported previously[2], a major step introduced by this laboratory in the separation of tumour-specific antigens is the elimination of normal antigenic components from the tumour antigen complement by absorption with antibodies produced against a large pool of normal tissues obtained from a pool of serum from four different horses.

The dynamics of this absorption in a system of soluble antigens and soluble antibodies was previously described and all the inherent difficulties of this totally unknown system discussed. The recent introduction in our methodology of a form of insolubilized immune γ-globulin[4] greatly simplified and improved the absorption of normal components from the tumour antigen complement, free of residual horse γ-globulin.

Diazotization of horse hyperimmune anti-normal human tissue γ-globulin results in cross-linking of the globulin to an insoluble form (polyglobulin) which can be used as a chromatographic column bed[4,6]. This communication describes the use of such a column for the separation of tumour-specific antigens from breast carcinoma.

Sources of breast carcinoma: 1, 2 and 3: 60 g each of tumour tissue (adenocarcinoma of the breast, grade II) obtained from surgical specimens (mastectomies); 4: 60 g of a liver totally and diffusely infiltrated by cells of adenocarcinoma of the breast.

A total of 240 g of clean tumour tissue was homogenized in glycine buffered saline, *p*H 10·4, and fluorocarbon as described elsewhere[1] and a solution containing 3·5 g per cent of protein obtained. This will here be referred to as unabsorbed breast antigen.

Equine hyperimmune anti-tumour γ-globulin (*HTU GG*, Lot. No. 27 GG33) with a precipitin titre, in single-gel diffusion, of 2^{-5} against the inoculating antigen. This antigen was obtained by fluorocarbon treatment of a large pool of solid tumours in which breast adenocarcinomas were largely represented[2].

Equine hyperimmune anti-normal γ-globulin (*NHGG*, Lot. No. 4,5 GG21) with a precipitin titre of 2^{-7} against the inoculating antigen which was obtained by fluorocarbon treatment of a pool of nearly every normal tissue in the human body[2].

Copolymerized NHGG: Insolubilization of the anti-normal γ-globulin by cross-linkage with tetrazobenzidine bridges was obtained as described elsewhere[4].

A chromatographic column of this insoluble *NHGG* was prepared with 30 g of γ-globulin. This column was equilibrated with 0·1 M phosphate buffered saline, *p*H 7·2, at 2° C. This temperature is maintained by a jacket of crushed ice surrounding the column.

An aliquot of 180 ml. of unabsorbed breast tumour antigen containing 6·3 g of protein in glycine buffered saline *p*H 10·4 was placed over the column and allowed to soak through by removing 180 ml. of phosphate buffered saline (fraction 0). The column was then incubated for 1 h at 2° C and several fractions of 100 ml. each collected. Phosphate buffered saline was added in amounts of 100 ml. to promote descent of each new fraction.

The size of the γ-globulin column was calculated to exceed five times the weight/weight ratio of the precipitin titre previously obtained in single-gel diffusion hæmatocrit tubes[5].

Each fraction was tested in single gel diffusion for quantitative precipitation against *HTUGG* and *NHGG* and in double gel-diffusion for identification of reactants. Protein concentrations were determined by the absorption at 280 mμ wave-length.

Table 1 and Fig. 1 summarize the results obtained. In them it is apparent that: (1) The unabsorbed tumour antigen complement consists of 8 antigens, 2 of which are in common with normal tissues (Fig. 1, No. 1). (2) Antigens reacting against anti-normal γ-globulin do not appear in any of the collected fractions. (3) Increase in protein concentration results in increase in the number of tumour antigens while normal antigens remain undetected. (4) The largest number of tumour antigens (that is, 6) equals the number of antigens in the unabsorbed original

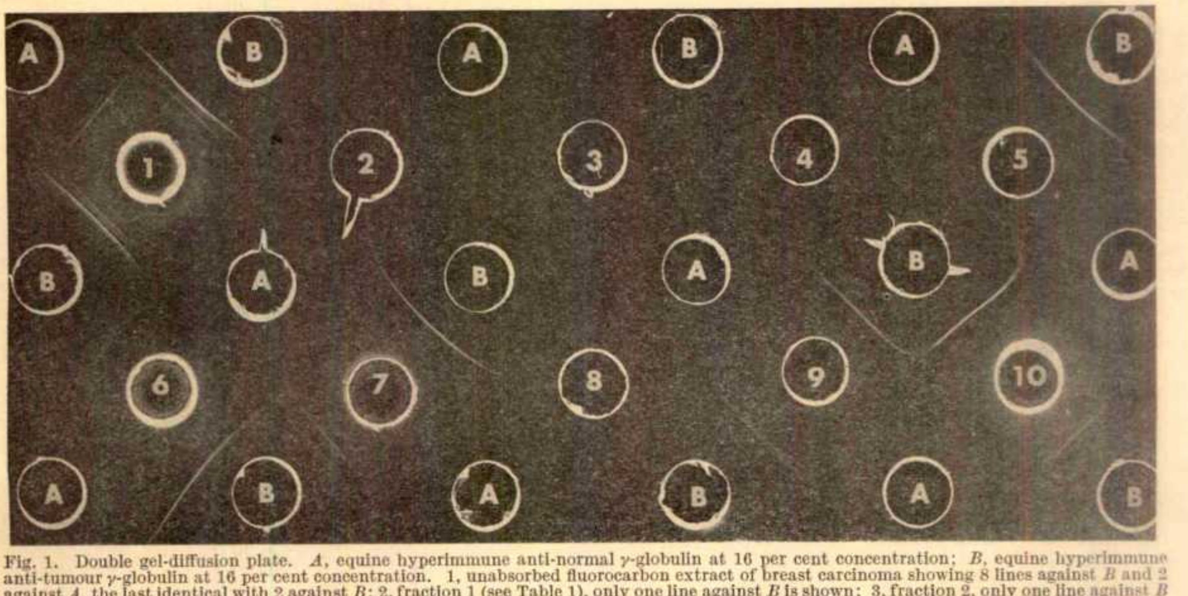

Fig. 1. Double gel-diffusion plate. *A*, equine hyperimmune anti-normal γ-globulin at 16 per cent concentration; *B*, equine hyperimmune anti-tumour γ-globulin at 16 per cent concentration. 1, unabsorbed fluorocarbon extract of breast carcinoma showing 8 lines against *B* and 2 against *A*, the last identical with 2 against *B*; 2, fraction 1 (see Table 1), only one line against *B* is shown; 3, fraction 2, only one line against *B* is shown; 4, fraction 3, a faint line which could be seen in the plate did not reproduce in the photograph; 5, fraction 4, two lines against *B*, only; 6, fraction 5, six lines may be seen against *B*, none against *A*; 7, fraction 6, at least 4 lines may be counted against *B*, none against *A*. Other numbers are not relevant to the context of this communication

Table 1. IMMUNOCHROMATOGRAPHIC SEPARATION OF BREAST CARCINOMA ANTIGENS ON A COLUMN OF CROSS-LINKED HORSE ANTI-NORMAL (HUMAN) γ-GLOBULIN

Fraction	Titre in single gel-diffusion		Protein concentration g%	No. of lines in double gel diffusion (Fig. 1)	
	Against *NHGG*	Against *HTUGG*		Against *NHGG*	Against *HTUGG*
Unabsorbed tumour antigens	2^{-7}	2^{-5}	3·5	2	8
0 (1st 100 ml.)	0	0	0·0	0	0
1 (2nd 100 ml.)	0	2^{-3}	0·070	0	1
2 (3rd 100 ml.)	0	2^{-3}	0·062	0	1
3 (4th 100 ml.)	0	2^{-3}	0·051	0	1
4 (5th 100 ml.)	0	2^{-4}	0·480	0	2
5 (6th 100 ml.)	0	2^{-4}	1·680	0	6
6 (7th 100 ml.)	0	2^{-5}	0·600	0	4

NHGG, equine hyperimmune anti-normal γ-globulin; *HTUGG*, equine hyperimmune anti-tumour γ-globulin.

extract (that is, 8) which react with anti-tumour globulin (Fig. 1, No. 1 and *B*) minus the antigens in the same (that is, 2) reacting with antinormal globulin (Fig. 1, No. 1 and *A*). Analysis of the protein complement of breast tumour tissue reveals only antigenic acquisition but no antigenic deletion or deviation, 70 per cent of the protein being of normal antigenic nature.

These results seem to indicate that this method resulted in the resolution and large-scale preparation of specific antigens from human adenocarcinoma of the breast.

Effect of Early Thymectomy on Development of Mammary Tumours in Mice

IT is now well established that the thymus plays an important part in the development of immunological competence in mammals. For example, in the mouse, removal of the thymus within the first 24 h after birth results in a serious impairment of the capacity to produce circulating antibody and the ability to reject allogeneic grafts of normal or neoplastic tissues. In addition, these mice also develop a wasting syndrome ending in early death[1-7]. Surgical ablation of the thymus at 6 and up to 35 days of age also produces a state of immunological impairment, which is more severe when thymectomy is performed earlier in life. These animals do not develop the wasting syndrome and have a life-span comparable with that of non-thymectomized controls[8-10].

Since development of mammary tumours in susceptible strains of mice depends at least in part on the presence of an infectious agent transmitted by the mother to the progeny via the milk (Bittner's virus), it was considered of interest to ascertain whether or not thymectomy performed at 6 days of age in mice of a high cancerous strain would affect the spontaneous development of mammary tumours in these animals.

Two groups of female mice of the *C3H/Bi* strain were used. One group of animals was thymectomized 6 days after birth by the technique routinely used in this laboratory[11], and the other left as non-thymectomized controls. After surgery, mice were raised by their own mothers and weaned at 30 days of age, at which time the thymectomized and non-thymectomized mice were housed in plastic cages in groups of 4–5 female mice per cage. One normal male of the same strain was introduced into each cage and the mice were allowed to breed. Breeding behaviour was assessed by the number of litters born from each mother in both groups (Table 1). The mice at all times had free access to 'Purina Laboratory Chow' and tap water.

The incidence of spontaneous mammary tumours in both groups was determined by weekly inspection of each individual mouse. The age of the mouse was recorded at the time a tumour appeared.

Table 1. INCIDENCE OF SPONTANEOUS MAMMARY ADENOCARCINOMA IN THYMECTOMIZED AND NON-THYMECTOMIZED FEMALE MICE OF THE *C3H/Bi* STRAIN KEPT AS BREEDERS

Group	No. of mice	Breeding behaviour. No. of litters born (mean)	No. of mice with cancer	%	Mean cancer age (days ± *S.D.*)
C3H normal	73	4·4	69	94·5	276 ± 5·04
C3H thymect. at 6 days of age	26	4·6	15	57·6	335 ± 16·2

The results of these experiments (Table 1) demonstrate that, in the group of *C3H* mice thymectomized at 6 days of age, 57·6 per cent of the females developed spontaneous mammary tumours as compared to 94·5 per cent in the group of non-thymectomized controls. This difference is statistically significant at the 1 per cent level. Furthermore, thymectomized mice developed tumours significantly later than non-thymectomized controls. In the former group the average cancer age was 335 ± 16·2 and in the latter 276 ± 5·04 days.

Although the interpretation of these results must remain a matter of conjecture at the present time, a few pertinent comments are in order. According to Bittner[12] development of breast cancer in mice is dependent on the concurrent effect of three factors, namely, inherited susceptibility, proper hormonal stimulation, and the presence of the mammary tumour 'agent' or virus which is transmitted from the mother to the offspring by the milk. Since the inherited susceptibility for tumour development is genetically controlled and presumably does not change after thymectomy, it might be that the mechanism operating in cancer prevention by early thymectomy, as reported herein, could be related to an alteration of the hormonal stimulation for tumour development. Another possibility is that the thymus may be essential early in life for proper growth and multiplication of the mammary tumour virus. Finally, the development of mammary tumours could be related to the immunological responsiveness of the host animal to the virus. It has been shown recently that neonatal thymectomy in mice greatly reduces the mortality resulting from inoculation with lymphocytic choriomeningitis virus (LCM), and this reduction in mortality is the result of decreasing the host response to the virus[13,14]. Perhaps the development of spontaneous mammary tumours in mice is also in part dependent on a similar mechanism.

Experiments designed to investigate these and other possibilities are in progress.

RADIOBIOLOGY

A Cellular Component of Thymic Function

THYMECTOMY in the new-born[1,2] or in the adult irradiated mouse[3] leads to a long-lasting suppression of the ability to respond to primary antigenic challenge. It has been shown in both instances that thymus grafting is effective in restoring immunological competence[2,4,5] and, furthermore, when using a cytologically marked thymic graft, it has been possible to detect cells derived from the graft in the spleen and lymph nodes[2,5]. It has, therefore, been suggested[5] that it may be these donor cells which are directly responsible for the recovery of the primary immune response in thymus-grafted animals.

In order to test this possibility, six *CBA* male mice were thymectomized[6], irradiated (850 r.) and given 5 million syngeneic bone marrow cells. On the day of irradiation, each mouse was grafted under the kidney capsule with a single thymus lobe from a 1–3-day-old *CBA/T6T6* mouse. (The cells of *CBA/T6T6* mice are characterized by a pair of small marker chromosomes.) Twenty-eight days later half the mice were given an injection of sheep red cells (0·2 ml. of a 20 per cent suspension in Alsever's solution). Three days after challenge the animals were killed and cytological preparations were made following the methods of Ford and Hamerton[7] and Rothfels and Siminovitch[8]. The slides were analysed and the results are shown in Table 1.

Table 1. CYTOLOGICAL ANALYSIS OF SPLEENS FROM *CBA* MICE BEARING A CYTOLOGICALLY MARKED (*CBA/T6T6*) THYMUS GRAFT

Uninjected mice				Mice injected with sheep cells			
Mouse No.	No. of cells scored	% *CBA*	% *CBA/T6T6*	Mouse No.	No. of cells scored	% *CBA*	% *CBA/T6T6*
1	38	89·5	10·5	4	50	66·0	34·0
2	46	100	0	5	50	80·0	20·0
3	47	93·6	6·4	6	50	86·0	14·0

There is a significant increase ($P < 0·05$) in the number of marked donor cells found in the spleens of the injected mice. This would indicate that cells, presumably derived from the thymic graft, are capable of dividing in response to antigenic stimulation. It is not, therefore, unreasonable to suppose that the thymus graft restores immunological function, at least in part, by itself providing appropriate cells. The implications of this preliminary finding are the subject of further investigation.

Removal of Radiocæsium from Beef

Two of the long half-life nuclides of major interest in food and feedstuffs which result from fall-out are radiostrontium and radiocæsium. Cæsium is almost always associated with the other alkali metals and particularly resembles potassium. Hood and Comar[1] demonstrated that ^{137}Cs is absorbed and distributed rapidly in the soft tissues and the body fluids, including milk. In distribution investigations, these authors found that the greatest accumulation of radiocæsium occurred in the muscles as compared with other body tissues. Ekman[2] reported that radiocæsium accumulated more rapidly in the physiologically active muscles than in inactive muscles; however, ultimately the inactive muscles were reported to have a higher content.

Using four human subjects, Richmond, Furchner and Langham[3] found that radiocæsium had a biological half-life of about 135 days. Other workers have reported half-lives varying from 100 to 150 days. Combined with the fact that radiocæsium has a considerable biological half-life in man and that the two most important nuclides, ^{134}Cs and ^{137}Cs, have physical half-lives of approximately 2·8–30 years, respectively, it becomes increasingly important to consider the significance of radiocæsium intake from the point of view of health.

In the inland arctic regions, caribou and reindeer are the main sources of meat and milk for the Eskimos and the Lapland tribes. In the arctic these herbivorous animals subsist essentially on lichens which are known to concentrate radiocæsium from fall-out. Meat from these areas has been reported to contain significant levels of radiocæsium. Whole-body counting investigations of human beings by Palmer *et al.*[4,5] and Liden and Andersson[6] in Alaska, Finland and Sweden have demonstrated that these arctic inhabitants have high radiocæsium body burdens as compared to other peoples. In northern regions of the world, some uncomplicated treatments for removing ^{137}Cs and ^{134}Cs from muscle may now be of value. In the temperate zones also, if cattle and other domestic animals grazed on pasture contaminated with heavy amounts of fall-out and then had to be utilized for human consumption, knowledge of some removal techniques would be valuable. Meyer *et al.*[7] reported that the loss of ^{134}Cs from cooked beef muscle was related to the amount of water used and the exposed surface area. Average activity removed was 19 per cent from oven roasts, 43 per cent from braised steaks, and 53 per cent from stew. Additional treatments prior to cooking may be of value to reduce the level of radiocæsium in the tissue. Data are reported here on the removal of radiocæsium from raw beef muscle from a heavy steer which had received intravenously a 10-mc. dose of ^{134}Cs.

Since radiocæsium accumulates in the soft tissue, it must be to a degree associated with the muscle and plasma proteins in a manner similar to the relationship sodium and potassium ions have with these proteins. If radiocæsium associates with proteins, then the degree of association might be affected by changes in *p*H. Cæsium-134 was more easily leached from cubed samples of longissimus dorsi (L.D.) at the isoelectric point of rigor, *p*H 5·5, than from samples at *p*H 6·4 and 5·7 removed from the steer carcass at earlier post-mortem times. After subjecting the leaching solutions to ultrafiltration[8] and counting portions of the filtrate and residue, it was found that the soluble protein fraction had the same c.p.m./ml. as did the filtrate; thus this experiment failed to demonstrate any association between ^{134}Cs and the leachable protein.

Variable volumes of leaching solution (0·85 per cent sodium chloride) had little effect on the total amount of activity removed from meat cubes over a given period of time. The most effective removal treatments incorporated agitation and replacement of the leaching solution. In four changes of saline solution and a total of 2 h agitation, 63 per cent of the ^{134}Cs was removed from 2·5-cm slices of L.D. muscle. Twenty-eight per cent of the ^{134}Cs was removed from the steaks during the first 30-min period of agitation (Fig. 1). When ground chuck was treated similarly, 75 per cent of ^{134}Cs was leached from the meat

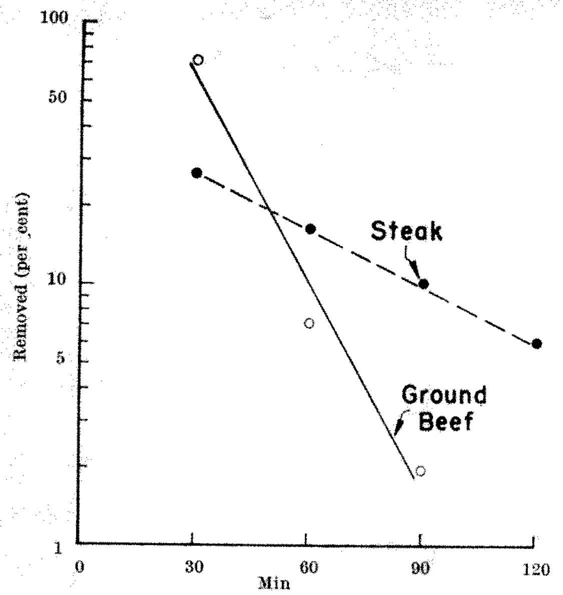

Fig. 1. Removal of ^{134}Cs from steak and ground beef during successive 30-min periods

in the initial 30-min period of agitation. The ground chuck lost 33 per cent of its total nitrogen in three 30-min treatments. The steaks lost 6 per cent total nitrogen when given 4 half-hour periods of agitation and salt solution changes.

The resulting ground beef had a very pale greyish-tan colour. The surface of the slices of L.D. had some faint pink areas while their interior had a red though faded colour increasing in intensity towards the centre. Steaks and ground beef from animals not dosed with ^{134}Cs and given the same agitation-leaching treatment were edible. After grilling, ground-beef patties had little flavour and were very light in colour; however, the steaks retained some of the delicate beef flavour and had a light colour similar to that of cooked pork.

In tests with flowing tap-water, approximately 81 per cent of the ^{134}Cs was removed from one-inch cubes of round in 12 h and over 99 per cent in 60 h. Freezing had little effect on the ^{134}Cs content of chuck. After accounting for drip loss and sampling, the average c.p.m./g were the same in thawed chuck roasts as in fresh.

In contrast to cæsium, strontium nuclides concentrate in the skeletal tissue. Strontium-89 and ^{90}Sr can be eliminated almost completely by boning the animal carcass[9]. Cæsium radionuclides can be removed in part from beef by cooking if the drippings and juices are discarded and by the treatments described in this communication. In areas of the world where cooked meat is eaten, a series of treatments including boning, a precooking treatment of leaching and agitation, and cooking would result in edible meat with reduced protein content and with approximately a 90 per cent reduction in radiostrontium and radiocæsium.

BIOLOGY

Mechanism of Apical Dominance in Plants

THE phenomenon of apical dominance in plants has been the subject of considerable research over the past thirty years (reviewed by Audus[1]), yet there is still no general agreement as to the nature of the mechanism involved. Much of the work on this problem has been based on the assumption that the inhibiting influence of the apex is mediated either directly or indirectly by auxin. There is, however, considerable evidence that nutritional factors are also involved and that the expression of apical dominance is at least partly determined by the nutritional status of the plant.

This effect of nutrition was well illustrated in a recent investigation of the influence of the nitrogen supply on the growth and development of *Agropyron repens* (L.) Beauv. In this investigation, which is described more fully elsewhere[2], it was found that the inhibiting influence of the rhizome apex on the growth of the lateral buds could be quite precisely controlled by varying the nitrogen level. At low nitrogen levels bud growth was completely inhibited but could be induced to occur by removing the rhizome apex; whereas, at a high level of nutrition, the onset of dormancy was eliminated, all the buds developing as lateral rhizome branches on the intact plant.

This nutritional effect is similar to that reported by Gregory and Veale[3], who showed, in experiments with flax, that the degree of apical dominance was largely dependent on the nitrogen and carbohydrate nutrition of the plant. While these workers concluded that nutrition was the main factor in apical dominance they also postulated, on the basis of anatomical observations, that auxin produced in the stem apex may inhibit the buds indirectly by preventing the formation of their vascular connexions with the main axis, thus depriving them of an adequate nutrient supply. This hypothesis is but a slight modification of that proposed earlier by van Overbeek[4], who suggested that auxin may impede the flow of nutrients to the buds by causing some kind of blockage of the vascular supply.

Neither of these hypotheses, however, can claim any direct experimental support. Indeed, there is now considerable evidence that auxin plays an essential part in the differentiation of vascular tissue[5], and may, at least in certain species, be a limiting factor in its formation[6]. When this function of auxin is considered in relation to Gregory and Veale's hypothesis, it would seem that the development of vascular connexions to the buds is more likely to be limited by the supply of auxin from the bud itself, rather than to be suppressed by auxin from the stem apex. Thus, the variation observed by these workers in the development of the bud vascular connexions at different nodes of the stem may well reflect differences in the amount of auxin produced by the buds prior to the onset of dormancy. It is, therefore, suggested, merely as a working hypothesis, that the initial stimulation of bud activity when the stem apex is removed is due directly to the increased availability of nutrients. This stimulation of growth and metabolic activity might be expected to result in an increase in auxin production which, in turn, may enhance the flow of nutrients to the bud by promoting a greater development of the vascular connexions.

This hypothesis is supported, first, by van Overbeek's[4] observation that, in *Pisum sativum*, decapitation of the stem is followed within 12 h by a rise in the auxin content of the axillary buds; and, secondly, by the work of Moreland[7], who noted in experiments with *Phaseolus vulgaris* that within 48 h of removing the stem apex, and before the cotyledonary buds had increased appreciably in size, the vascular supply to the buds had been strengthened. Moreover, the cyclical nature of this postulated mechanism, in which nutrient supply, growth, auxin production and vascular tissue formation are regarded as interdependent, and the role attributed to irreversible anatomical changes agree well with the observation that bud growth, once established, cannot easily be arrested[1,4,8].

It is also assumed, on this hypothesis, that the auxin produced by the stem apex performs a similar function and thus, by controlling the differentiation of the vascular tissue in the stem, may determine, at least to some extent, the capacity of the apex to monopolize the nutrient supply. While such a mechanism may serve to maintain the dominance of the apex, the fact that the stem apex is initiated before the lateral meristems in the ontogeny of the plant may well provide it with a sufficient initial advantage in competing for nutrients to account for the dominance which it later achieves as the pattern of growth is established.

Secretion Masses in the Nuclei of the Caudal Neurosecretory Cells of the Teleost *Albula vulpes*

'NUCLEAR secretion' has been reported by a number of students of neurosecretory cells, especially in fish hypothalamic neurones[1-7]. Neurones exhibiting similar characteristics have been described in the caudal neurosecretory system of two isospondylous teleosts: *Albula vulpes* and *Elops hawaiensis*[8,9]. The caudal neurones of many teleosts may possess various kinds of nuclear inclusions, generally less prominent than those of *Albula* and *Elops*, and not necessarily considered as 'secretion'[10-12]. Inasmuch as the actual production of proteinaceous secretory product within the nucleus is not consonant with the present conception of the protein-secretory cell, we undertook a re-examination of the caudal neurosecretory neurones in *Albula vulpes*, the Hawaiian 'oio' or bonefish, with the electron microscope.

The nuclei of the caudal neurosecretory neurones of *Albula* are highly polymorphic. In light-microscope preparations stained with acid violet[13] densely staining 'inclusions' are seen in many nuclei (Fig. 1*A*); the axon terminals around capillaries in the neurohæmal organ of this system—the urophysis—are also intensely coloured. Other cells show cytoplasmic invaginations, some of which appear to be surrounded completely by the nucleus. Although some of the inclusions are not obviously connected with the perinuclear cytoplasm, a canal is probably present. If the canal happens to be in the plane of section, it would be indiscernible (see Fridberg[11]).

On the ultrastructural level, the nature of the nuclear 'inclusions' previously interpreted as secretion masses soon became apparent (Fig. 2). The masses are intranuclear cytoplasmic invaginations (*ICI*) and are characterized by the presence of the usual cytoplasmic organelles: rich endoplasmic reticulum with dilated cisternæ, mitochondria, Golgi membranes, and ovoid lysosome-like bodies. Elementary neurosecretory granules were also present, occasionally associated here, as in the perinuclear cytoplasm, with Golgi membranes[14,15]. The elementary granules were present in higher concentration in the 'intranuclear' cytoplasm than in the more peripheral

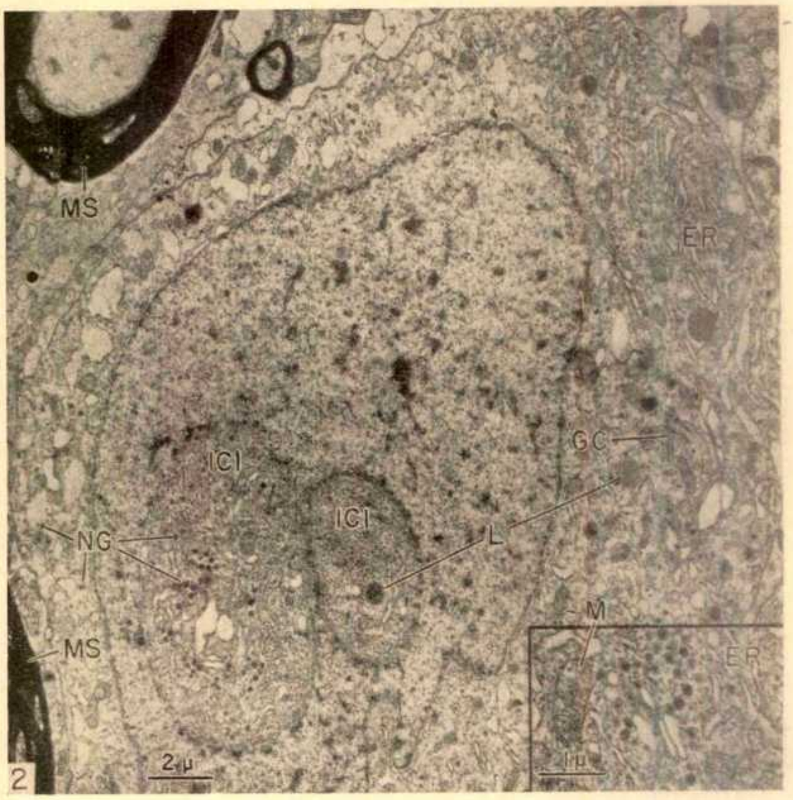

Fig. 2. Electron micrograph of portion of caudal neurosecretory neurone with two intranuclear cytoplasmic invaginations (*ICI*). Inset: intranuclear cytoplasmic invagination with concentration of neurosecretory granules (*NG*); *ER*, endoplasmic reticulum; *GC*, Golgi centre; *L*, possible lysosomes; *M*, mitochondria; *MS*, myelin sheaths

cytoplasm (Fig. 2); this might account for the intense staining with acid violet.

Whether all varieties of previously described intranuclear materials, especially the colloid droplets[1,4] in hypothalamic neurosecretory neurones, are intranuclear cytoplasmic invaginations is still uncertain. Colloid droplets are seen extracellularly in the caudal neurosecretory system of various fishes (for example, *Paralichthys californicus*) and may represent products of cell degeneration.

The intranuclear cytoplasmic invaginations were most prevalent in animals taken from sea-water 'ponds'. Fish caught in the open sea had fewer intranuclear cytoplasmic invaginations, generally located in small cells close to the urophysis. The more anteriorly located large cells usually possessed extensively multilobate nuclei (Fig. 1*B*). Some nuclei were obviously intermediate stages between those with intranuclear cytoplasmic invaginations and the multilobate types. The cytoplasmic regions bordering on intermediate nuclei stained strongly with acid violet. One group of adult females taken from the open sea showed no sign of intranuclear cytoplasmic invaginations, but all caudal neurosecretory cells contained complexly lobate nuclei. The variable nuclear morphology in *Albula* may be correlated with habitat, but also possibly with age and/or sexual maturity. The open sea fish were larger and had better developed gonads than the 'pond' fishes.

In view of the still elusive functions of the caudal neurosecretory system and the urophysis[8,16] the cytological alterations seen in *Albula* may be indicative of actions unrelated to its suggested ionoregulatory role[17] and merit further investigation.

Synchronization of Hatching in American Bobwhite Quail (*Colinus virginianus*)

IT is known that chicken embryos show great variation in their rate of development. This is due to three main factors: variations in the latent period, variations in the environmental factors of incubation and the inherent variations of the embryos themselves[1,2]. Some, or possibly all, of these factors are likely to occur under natural conditions within a single clutch of eggs, and particularly in species which incubate large clutches.

Given these variations, it seems remarkable that the young of many species of birds hatch at the same time. Among British game birds this is reported for the common quail (*Coturnix coturnix*), the common partridge (*Perdix perdix*), the pheasant (*Phasianus colchicus*) and the red grouse (*Lagopus scoticus*)[3]. Similarly it has been found here that when a clutch of the American bobwhite quail (*Colinus virginianus*) is incubated artificially, the eggs will hatch within an hour or two of each other. This synchronization of hatching (emergence of the chick from the shell) occurs in spite of considerable variability in the previous easily detectable stage of 'pipping'; that is, the appearance of one small hole in the shell indicating that pulmonary respiration has already begun. In the bobwhite quail eggs normally pip about two days before hatching.

The experiment described here shows that it is possible not only to shorten the normal incubation period (23 days) by incubating embryos in contact with others 24 h older, but also, by doing so, to synchronize the final stages of development so that all embryos hatch at the same time.

Eggs were taken from two pairs of quail, each one being removed from the parents soon after laying and stored at a temperature of approximately 18° C for up to 14 days. Clutches were incubated in a 'Curfew' observation incubator run at 40·5° C. The eggs were incubated in clutches of 2, 3, 4, 5, 10 and 11 eggs, progeny from the two pairs being kept separate. Seven eggs were incubated singly. Inside the incubator clutches were separated by distances of at least 4 in., but within each clutch eggs were in contact with each other. In all clutches one unincubated egg was placed within the clutch 24 h late. The eggs were observed regularly from the 20th day onwards and notes were made of the approximate times of pipping and hatching of each egg.

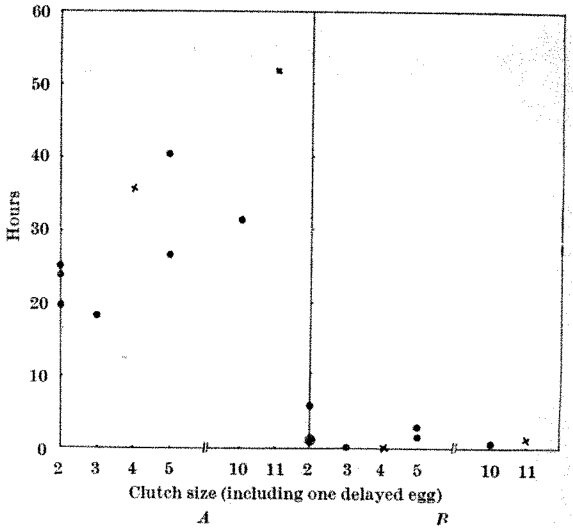

Fig. 1. *A*, Interval between pipping of first and last eggs; *B*, interval between hatching of first and last eggs. ●, Eggs from pair *A*; ×, eggs from pair *B*

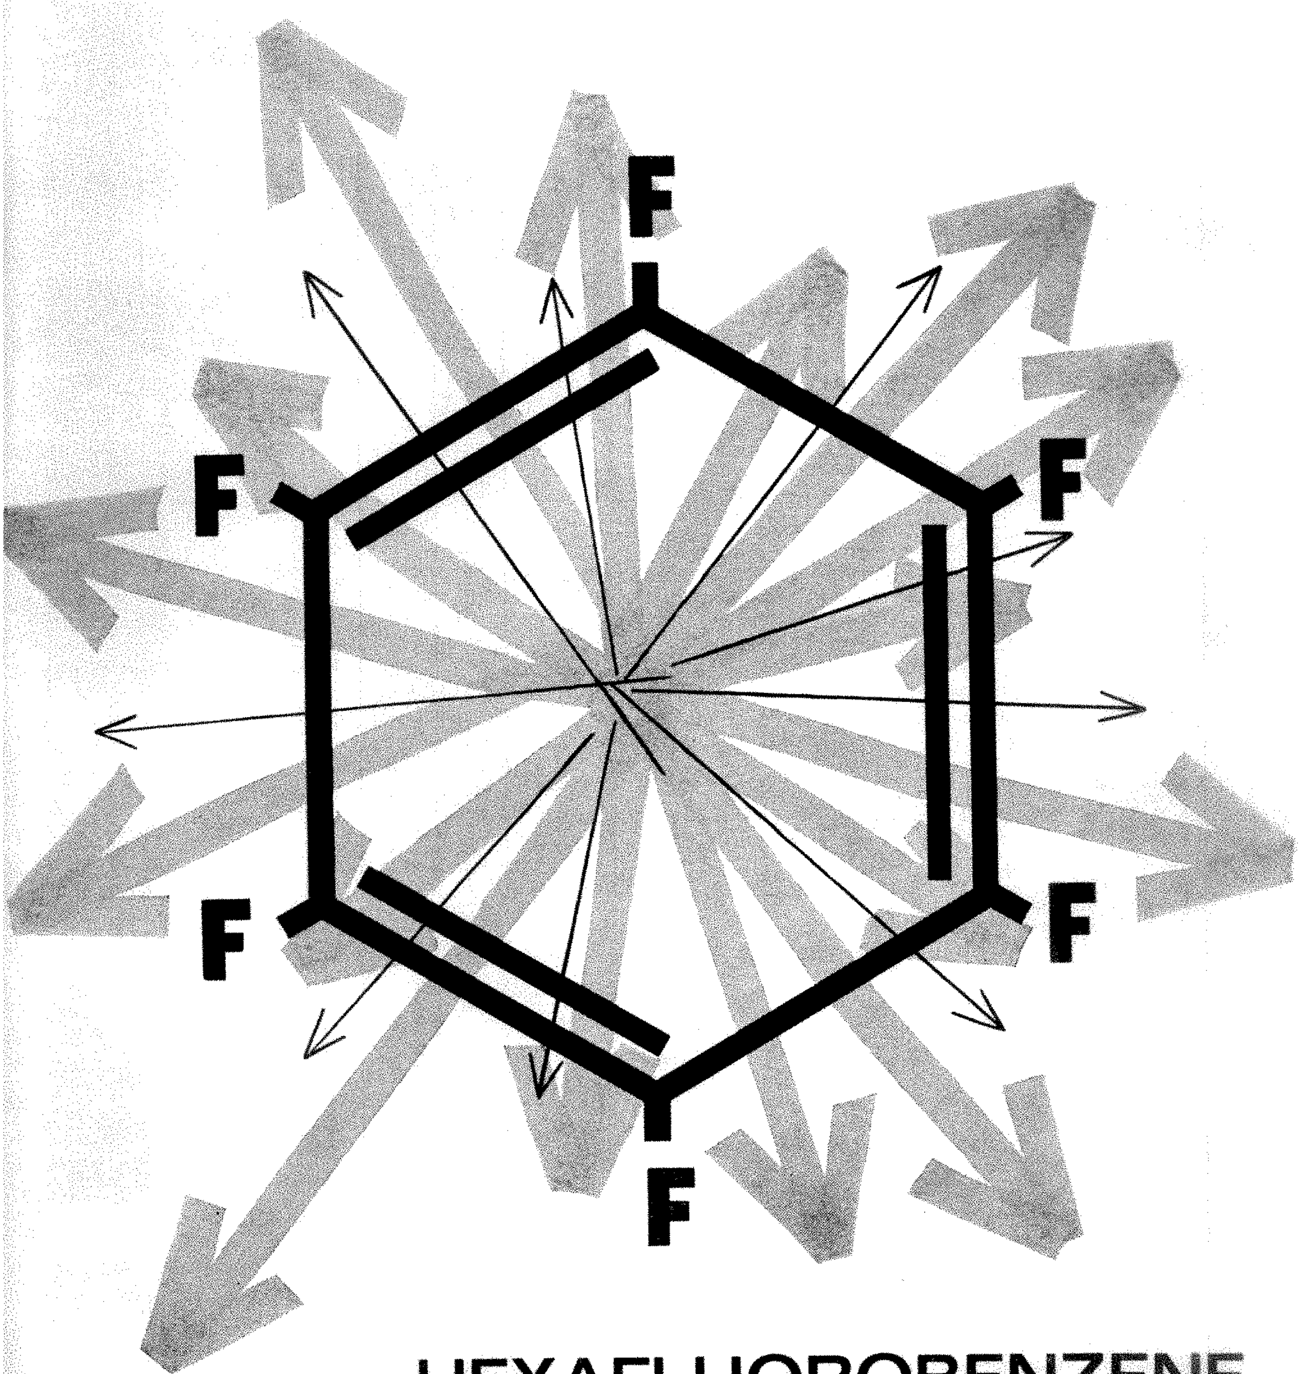
Results are given in Fig. 1. Fig. 1*A* shows the time-interval between the pipping of the first and last eggs in each of the nine clutches observed. The last egg to pip was, in all cases except one, the delayed egg. This time interval varied from 18 to 52 h, suggesting that each egg pipped at approximately its 'normal' time, that is, on the 21st or 22nd day of incubation. Fig. 1*B* shows, however, that the time-interval between the hatching of the first and last eggs in these same nine clutches was never more than 6 h. The mean number of hours between pipping and hatching was 23 for the nine delayed eggs and 44 for the seven eggs incubated singly. This, considered in conjunction with Fig. 1, suggests, therefore, that the delayed embryos accelerated their development between



HEXAFLUOROBENZENE

74 compounds now available

These compounds are being made available world-wide for the first time, following the discovery by Imperial Smelting Corporation Limited and at the University of Birmingham, of a new and attractive synthetic route. They open up exciting possibilities in such fields as polymers, pharmaceuticals, dyestuffs and agricultural chemicals, where the presence of a fluorinated aromatic ring may lead to novel properties. Many companies and university research departments are taking experimental quantities of these fluorocarbon compounds and carrying out their own programmes of investigation.

pipping and hatching, and that this shortening of the incubation period is due to the proximity of the more advanced eggs in each clutch.

These results are consistent with the view that there is, in this species, a mechanism acting between eggs which tends to synchronize the embryos' development towards the time of hatching, by speeding up the retarded ones. The nature of this mechanism is under consideration.

✓ Mammalian Intrafusal Muscle Fibres

RECENT histological investigations of cat muscle spindles[1-3] have established the presence of two types of muscle fibre, the large nuclear-bag fibres and the smaller and more numerous nuclear-chain fibres (Fig. 1*A*). Boyd[3] maintains that each type of muscle fibre receives its own pattern of innervation, there being, in particular, a segregation in the size distribution of the fusimotor supply. However, earlier work by one of us[4] described spindles in the quadriceps femoris of the rabbit which did not show this structural duality, since they were composed of nuclear-bag fibres only. We wished to ascertain the validity of this observation, and to determine the extent to which the muscle-fibre content of cat spindles represents the typical mammalian condition.

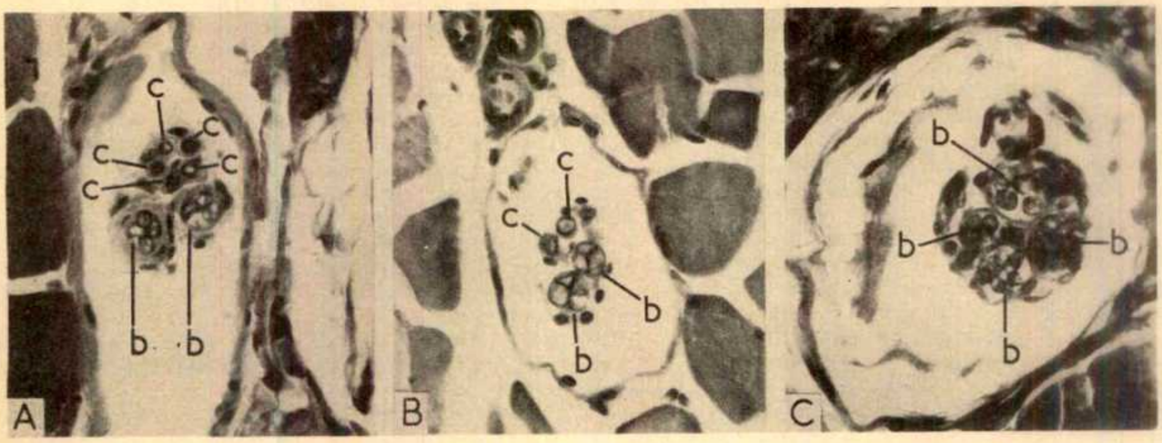

Fig. 1. Transverse sections through the equatorial region of spindles from cat soleus (*A*), rat rectus femoris (*B*), and rabbit vastus intermedius (*C*) muscles. Nuclear-chain muscle fibres (*c*) outnumber nuclear-bag muscle fibres (*b*) in the cat (2 bag : 5 chain fibres); are present in equal proportion in the rat (2 bag : 2 chain fibres); and are absent in the rabbit (4 bag fibres only). (10μ paraffin sections stained with hæmatoxylin and eosin; × *c*. 410)

Fourteen spindles from rabbit hind-limb muscles were traced from end to end in serial transverse section, 3 from vastus intermedius, 3 from tenuissimus, and 8 from soleus. All spindles possessed nuclear-bag fibres only, the most frequent number being 4 (Fig. 1*C*). This was also the case in 3 spindles from the vastus intermedius of a hare, and in 3 out of 6 spindles from a rabbit fore-limb muscle (extensor digitorum communis). The other spindles in this sample, however, possessed 3 bag fibres accompanied by 1 or 2 chain fibres.

The typical fibre content of the rat spindle proved to be 2 bag and 2 chain fibres (Fig. 1*B*); 8 spindles from rectus femoris and 6 from soleus had this composition In a further 3 spindles from soleus the proportion of bag to chain fibres was 2 : 1, 3 : 1, and 2 : 3. Samples of 3 spindles taken from a thigh flexor muscle of a hedgehog, a tree shrew, and an armadillo had bag-to-chain fibre ratios of 2 : 2, 2 : 2, and 2 : 4 or 5, respectively.

Cooper and Daniel[5] found chain fibres to be the most numerous in the majority of human spindles sampled from neck and lumbrical muscles, but a few contained bag fibres only.

Nuclear-bag fibres are therefore a basic component of the mammalian spindle, whereas nuclear-chain fibres, though usually present in various proportions, may be lacking. A 'chain only' composition has been observed[2] in part of a cat tandem spindle, but this condition is probably aberrant. Evidently most spindles in a particular mammal possess a similar type of fibre composition, though other types may occur. Thus the lagomorph spindle is typically 'bag only', but combinations with chain fibres also occur; human spindles may lack chain fibres, though typically they are present in excess.

In the cat spindle the secondary endings lie predominantly on the nuclear-chain fibres[3]; in the rabbit spindle they lie on the nuclear-bag fibres mainly in the myotube regions[4] (hence the descriptive term 'myotube ending' suggested by Granit[6]). Both myotube and nuclear chain offer a similar substratum for the ending, and it is significant that the myotube regions in the rabbit are typically three to four times longer than those in the cat. The 'chain dominant' human spindle resembles the cat spindle in these respects[5]. As observed at or near the level of spindle entry, the motor innervation of the 'bag only' rabbit spindle is derived from both large and small fusimotor fibres (Barker[4]; Barker and Cope[7]; Ip, unpublished observations) as in the cat[3,7]. Matthews[8] has suggested that in the cat spindle these large and small motor fibres may represent functionally distinct types controlling the dynamic and static responses of the primary ending, respectively. The same correlation applied to the typical rabbit spindle would necessitate postulating a mechanism whereby this control could be achieved through the contraction of bag fibres only.

Dry Matter Production by Detached Ears of Wheat

Cereal yields have been shown to depend more on assimilation in the ears and flag leaves than on translocation into the grain of compounds manufactured or stored in other green parts of the plant[1]. Quantitative estimates of the relative contributions from the ears, the flag leaves or other green parts have been made by shading and defoliation methods[2–6], by enclosing ears in a transparent chamber supplied with $^{14}CO_2$ (ref. 7), or by following changes in the carbon dioxide content of air-streams entering and leaving such a chamber[8]. Such methods have been criticized for various reasons[9,10]. Buttrose and May[9] claimed that their technique with regulated floret numbers is free of many of these disadvantages, but Thorne[8] has shown that one of the assumptions on which the method is based is not valid and Lupton[11] has demonstrated that different results can be obtained if different numbers of florets are left on the ear. Obviously, this method of measuring net assimilation of cereal ears is also open to criticism.

Where it is necessary to measure the absolute rate of net assimilation by a cereal ear it is difficult to suggest any method better than those previously mentioned. In some situations, however, it may be enough to demonstrate that the net assimilation in the ears and flag leaves of one variety is relatively greater than in another. For this purpose the changes in dry weight of detached ears have been followed. The ears are taken shortly after anthesis from plants lifted and removed to the laboratory early in the morning while still fully turgid. The stems are cut several inches below the flag leaf node and trimmed under water to leave one inch of stem below this node. The experiments have been conducted out of doors with the ear preparations placed in batches of 72 in polythene-lined boxes (12 in. × 18 in. × 6 in.) covered with a hardboard lid pierced by holes 0·25 in. in diameter through which the stems pass. The boxes are filled with quarter-strength Long Ashton complete nutrient solution which is changed at three-day intervals. Since ear size accounts for much of the varietal differences in grain yield in wheat, conscious selection for uniformity of ear size in the detached ear preparations may, unwittingly, remove any varietal differences in ear assimilation that do exist. In these investigations the detached ear samples of each variety were, therefore, sorted into several size grades and equivalent numbers of each size grade were included in each sampling unit in the same proportion as that found to be typical of each variety.

Five experiments have been carried out with detached ear preparations from three winter and six spring wheat varieties in 1961 and 1962. The results of a 1962 experiment with the three winter wheat varieties 'Cappelle', 'Professeur Marchal' and 'Milfast' are given here. The detached ear preparations were made on July 11, 16 days after ear emergence. Twenty-four preparations from each variety were placed in each of four boxes and the flag leaf laminæ removed from twelve of them. This arrangement gives four replicates of a 3 × 2 split plot design. Two gatherings, each of six ears, were taken after 10 and 33 days, on July 22 and August 13. In addition, an initial sample of thirty ears of each variety was taken, and at the close of the experiment a further sample of thirty ears was collected from intact plants growing at the original sites in the field.

After 33 days it was found that the ear dry weights of the detached ear preparations with flag leaves were 1,508 mg for 'Professeur Marchal', 1,334 mg for 'Cappelle' and 1,164 mg for 'Milfast' (*L.S.D.* 129, $P = 0·05$). Ears of the same varieties from plants grown in the field weighed 2,067 mg, 1,600 mg and 1,483 mg, respectively, at the same date. Detached ear preparations have, therefore, produced 50 per cent less ear dry weight, an average increment of 491 mg, than field grown ears, average increment 863 mg, but still show varietal differences of the same size as those found for field grown ears. Similar results have been found in the other experiments. The dry weight contributions attributable to the flag leaf or to the ear plus peduncle have been calculated and these figures are given in Table 1 for the two sampling intervals and for the full 33-day period of the experiment.

Table 1. Contributions to ear dry weight (mg) from flag leaves (*F*) and ears plus peduncles (*E* + *P*) of detached ear preparations of 3 winter wheat varieties, Upperwood Farm, Reading, 1962

	Period 0–10 days		Period 11–33 days		Period 0–33 days	
	F	*E* + *P*	*F*	*E* + *P*	*F*	*E* + *P*
'Professeur Marchal'	191	107	36	273	227	378
'Cappelle'	137	114	62	198	199	312
'Milfast'	126	66	30	141	150	207
Mean of all varieties	149	96	43	204	192	299

L.S.D. ($P = 0·05$)	0–11 days	Period 11–33 days	0–33 days
(*a*) Between means of all varieties	11	18	20
(*b*) Between sub-treatment means within varieties (horizontal comparisons)	28	41	50
(*c*) Between treatment means between varieties (vertical comparisons)	20	29	35

Over the 33-day period the flag leaf contributions (192 mg) averaged only 64 per cent as much as the ear plus peduncle contributions (299 mg). Differences between these contributions were significant in each variety. Between varieties the flag leaf contribution of 'Milfast' (150 mg) was significantly lower than those of 'Cappelle' and 'Professeur Marchal' (199 and 227 mg respectively), which were not significantly different. The ear plus peduncle contribution of 'Professeur Marchal' (378 mg) was significantly greater than that of 'Cappelle' (312 mg), which in turn was significantly greater than that of 'Milfast' (207 mg). During the first 11 days of this period the flag leaf contributions (149 mg) averaged 155 per cent more than the ear contributions (96 mg), a trend evident in all varieties, but the difference between the contributions in 'Cappelle' was not significant. During this period the flag leaf contribution from 'Professeur Marchal' (191 mg) was significantly greater than those from 'Cappelle' and 'Milfast', which were similar (137 and 126 mg respectively), while the ear plus peduncle contributions of 'Professeur Marchal' and 'Cappelle' were similar (107 and 114 mg respectively) and both significantly greater than that of 'Milfast' (66 mg).

Over the 11–33-day period the flag leaf contributions were much reduced (43 mg), averaging only 21 per cent of the ear plus peduncle contributions (204 mg), the differences between the contributions being significant in each case. Observations at the time bear out the suggestion from these figures that flag leaves began senescing shortly after the eleventh day and were completely dried out by about the eighteenth day. Differences in the flag leaf contributions of the three varieties were slight, but the ear plus peduncle contribution of 'Professeur Marchal' (273 mg) was significantly greater than that of 'Cappelle Desprez' (198 mg), which, in turn, significantly exceeded that of 'Milfast' (141 mg). It may thus be concluded that the flag leaf contributes some 13·5 mg/day during the earlier part of the ear growth period, falling after the eleventh day to a value of 2·0 mg/day. The ear contribution was less than that of the flag leaf to begin with, averaging 8·7 mg/day, and, on the figures available, this was maintained at 9·3 mg/day during the last 22 days. Observations suggest that the actual rates would be higher than this for the first half of this period and lower for the last half as ear senescence became marked.

It is obvious that much of the physiology of these detached ear preparations requires to be investigated before it will be possible to consider them physiologically comparable to ears growing on an entire plant. The results of these investigations suggest, however, that such preparations may prove a convenient means of comparing the assimilatory capacity of the flag leaves and ears of different varieties and species of cereals. In addition they may prove a useful research tool in other subjects of physiological interest such as grain dormancy, the mineral requirements and water relations of the cereal ear and biochemical factors determining quality factors in wheat grains.

ENTOMOLOGY

Danger of Spraying Wooden Insect Cages with Melamine Resins

THE original cages used by us for rearing *Glossina austeni* were made of deal (coniferous softwood) by the local carpenter; the wood was left untreated. A precision wood-working firm was commissioned to make similar cages in large numbers. On their advice, mahogany plywood, exterior grade, was used, and the cages surface-sprayed with a melamine resin which would seal the wood against absorption of fæces and facilitate the washing of dirty boxes.

Twenty new, melamine-sprayed cages were first kept for three days in a room at 33° C so as to expel any residual solvent. Batches of about 25, 4-day-old, newly fertilized females were housed alternately in melamine-sprayed or deal cages; survival rates were recorded at days 14, 30 and 60 after fertilization (Table 1).

Table 1. TOXICITY OF MELAMINE RESINS

A comparison of survival rates among female *G. austeni* at days 14, 30 and 60 after mating when 3–4 days old

Cage type	Total No. of flies	Day 14 No. survived	Day 14 Survival %	Day 30 No. survived	Day 30 Survival %	Day 60 No. survived	Day 60 Survival %
Untreated deal cages	484	390	81	310	64	198	41
Melamine-sprayed plywood cages	476	363	76	262	55	140	29

The survival rate was lower in the new, melamine-sprayed cages, and, further, the differences at each age became progressively greater at 5, 9 and 12 per cent, suggesting that the melamine resin has slow-acting toxic properties. The difference at day 14 is not significant ($\chi^2 = 2 \cdot 65$; $0 \cdot 2 > P > 0 \cdot 1$). The difference at day 30 is significant ($\chi^2 = 8 \cdot 1$; $P < 0 \cdot 01$), as is the difference at day 60 ($\chi^2 = 13 \cdot 9$; $P < 0 \cdot 001$).

Melamine resin is a condensation product of melamine and formaldehyde, so presumably the formaldehyde is the toxic component. Since all surfaces of the mahogany plywood had been thoroughly sprayed with melamine resin, there can be no question of harmful emanations from either the mahogany or the bonding material used in plywood construction.

Since phenol-formaldehyde resins are now used as the bonding agent for plywood, a small test was undertaken to see if survival in untreated mahogany plywood boxes is worse than in deal boxes. The results suggest that survival is worse in the mahogany plywood boxes for the first seven weeks after manufacture, but not thereafter, whereas the melamine-sprayed cages are still toxic after 10 weeks.

✓ Effects of Brain and Corpus Cardiacum Extracts on Hæmolymph Trehalose of the Cockroach, *Periplaneta americana*

THE first report relating hormonal factors in insects to the regulation of a particular hæmolymph sugar was that of Steele[1]. He demonstrated that saline extracts of the corpus cardiacum of the cockroach *Periplaneta americana* (L.) cause about a 100 per cent increase in hæmolymph trehalose within 1 h after injection and the effect persists for several hours. The level of reducing sugar (glucose?) was generally lowered in these animals. Later, Steele reported that the extract accelerated the release of inorganic phosphate and that as hæmolymph trehalose was elevated fat-body glycogen declined[2]. Nerve cord glycogen also declined, but gut and muscle glycogen were unaffected. The interpretation is that the hormone appears to increase the activity of phosphorylase and produces a glycogenolic effect. More recently Bowers and Friedman[3] reported finding that in the South American cockroach, *Blaberus discoidalis* (Serville), administration of aqueous extracts of the corpus cardiacum significantly elevate both trehalose and glucose in the hæmolymph. They also found a decrease in fat-body glycogen 5 h after injection and extracts of the corpus allatum were also tested and found to be without effect. They note also that animals with heads tied off respond to the active extract, indicating that the effect is not mediated through other cephalic glandular material.

We wish to report here our observations which generally confirm and supplement these reports. A portion of this work has been briefly reported on elsewhere[4]. Adult male and female cockroaches, *Periplaneta americana* (L.), were examined. Tissue extracts were prepared from cockroaches that were rapidly anæsthetized by carbon dioxide gas and then chilled. The heads were removed and dissected in cold Hoyle's solution[5]. The corpus allatum (*CA*), corpus cardiacum (*CC*), brain or supraœsophageal ganglion (*B*), and subœsophageal ganglion (*S*) were placed on homogenizer pestles and frozen until used. The tissues were homogenized in Hoyle's solution, one tissue per 0·02 ml. Recipient animals were deprived of food for at least 18 h prior to injection. Six to ten animals constituted the experimental groups and each animal received 0·01 ml. of one of the tissue extracts (equivalent to one-half tissue). Control animals received Hoyle's solution only. After 1 h the animals were quickly immobilized by carbon dioxide, thoroughly chilled in a freezer, and their hæmolymph extracted (as a group) by the centrifugal method[6]. A 0·1 ml. portion of hæmolymph was then analysed for glucose (glucose oxidase–peroxidase method[7]) and trehalose (anthrone method of Wyatt and Kalf[8]).

Some of the results obtained during this work are shown in Tables 1 and 2. For analysis, only experiments in which all four tissues were tested simultaneously are shown here. A total of 25 experiments were conducted, but in the

majority of them only two or three tissues were tested. The results from all of them tend to fit the same general patterns as discussed here.

The significant elevation of trehalose following cardiacum administration confirms the observations of both Steele[1] and Bowers and Friedman[3]. The results in Table 1 for trehalose values were subjected to non-parametric analysis using rank order and yielded a coefficient of concordance of 0·75. After a continuity correction was applied, the order: $CC > B > CA > S >$ control, was significant ($P < 0{\cdot}01$). The comparable data of Table 2 show a rank order starting with *CC* and then *B*, but it is just significant at the 10 per cent level. The observation that the brain extract was generally effective also in elevating trehalose levels is noteworthy. Steele[1] tested the effects of brain, among other tissues, for this effect in 2 experiments and dismissed the slight increase in trehalose he found as probably due to traces of cardiaca tissue remaining attached to the brain. In our dissections the brains were carefully cleaned of any cardiaca tissue and we believe the hyperglycæmic effect observed is real. This could be interpreted to mean that the active factor of the cardiacum is produced by neurosecretory cells of the brain, if the result is viewed in the framework of the anatomical studies which suggest such a neuroendocrine relationship[9].

The results of glucose determination are too variable for statistical analysis so it is impossible to know if the cardiaca extracts tended to elevate glucose, as was the case in the results of Bowers and Friedman[3], but generally it was not depressed, as suggested by Steele[1].

Males given cardiacum extract usually had more hæmolymph trehalose than females. In 10 experiments in which males were tested with cardiaca extract, 7 groups had trehalose-levels greater than 1,000 mg per cent, whereas only 3 out of 9 groups of females had so high a level. Both groups were given extracts from male tissue. Thus, there may be a sex difference in responsiveness to the cardiaca factor.

A series of five experiments on the effects of starvation on the response to cardiacal extract showed that male animals starved for 8 days prior to injection fail to make any response to the hormone. Allatal extracts are also without effect. Furthermore, the levels of circulating trehalose in the control and experimental groups all were about 400 mg per cent, that is, about two-thirds the normal value.

The glucose values found in this work were higher than Steele's[1] and the trehalose values generally lower. The reason for these differences is probably relatable to strain differences and diet factors.

VIROLOGY

Inactivation of *MHV*-3 Virus by Intestinal Content and Intestine of Normal Mice

In previous work we reported on certain biochemical changes in experimental (*MHV*-3 virus)[1] and in human viral hepatitis[2,3]. This communication deals with the behaviour of *MHV*-3 virus[4], eliminated with bile in the intestine of infected mice. Because of evidence of virus inactivation in the intestine, experiments were also carried out on the effect of intestinal content and intestine from normal mice on *MHV*-3 virus.

Twenty mice of *NMRI*-stock, weighing about 10 g and fed on 'Altromin' diet, were inoculated intraperitoneally with 100 LD_{50} of *MHV*-3 virus. From mice killed 72 h after inoculation, samples were taken of the liver, gall-bladder bile, intestinal content of the first 5 cm of the small intestine as well as of the last 5 cm, fæcal content of the last section of the colon and, finally, fæces expelled. After addition of antibiotics the LD_{50} of the aforementioned materials was determined by the method of Reed and Muench[5].

The results given in Table 1 show a gradual decrease in the level of the virus from liver to expelled fæces. A striking difference in virus-levels can be observed, particularly between the bile and the first portion of small intestine and between the first and last portions of the small intestine. This finding, suggesting a possible inactivation of the virus during its pathway in the intestinal lumen, led us to perform the following experiments.

Table 1. Levels of Virus in Different Materials from Mice infected with 100 LD_{50} of *MHV*-3 Virus

Materials	LD_{50}
Liver	$10^{-7 \cdot 5}$
Bile	$10^{-6 \cdot 1}$
Smallintestine content (first 5 cm)	$10^{-2 \cdot 4}$
Smallintestine content (last 5 cm)	$< 10^{-1}$ *
Colon content (last section)	$< 10^{-1}$ †
Expelled fæces	$< 10^{-1}$ ‡

* At 10^{-1} dilution 4 mice of 10 used died.
† At 10^{-1} dilution 2 mice of 10 died.
‡ At 10^{-1} dilution no mortality was observed.

Mice were injected intraperitoneally (0·1 ml.) with 10-fold dilution of each material from 10^{-1} to 10^{-9} (10 mice for each dilution). The experiment reported in Table 1 is one of three which gave similar results.

Six mice of the *NMRI*-strain were used. From four of them, killed by decapitation, the whole intestinal content was taken and the intestine itself was thoroughly washed to remove any fæcal debris. From the two remaining mice the intestine was taken together with its content. These three materials (intestine, intestinal content and the two together) were carefully homogenized and tested for their inactivation power against *MHV*-3 virus. The virus, stored at −70° C as a 10 per cent suspension ($LD_{50} = 10^{-7 \cdot 6}$), was used in 10-fold dilution from 10^{-1} to 10^{-9}. Three series of these dilutions were prepared to contain a homogenate of the three different materials in final concentrations of 10 per cent. A fourth series was the control one (no homogenate added). All samples were incubated for 90 min at 37° C and frequently shaken. After incubation, virus-levels were determined in each sample as already indicated above[5].

The results presented in Table 2 show that virus-levels are much higher in the control series than in the presence of the different materials tested. This seems to show that virus can be highly inactivated by intestinal content and intestine. Liver and brain tissues from normal mice were used in the same experimental conditions to test whether

Table 2. Effect of Intestine and Intestinal Content on *MHV*-3 Virus Infectivity

Materials	LD_{50}
Virus	$10^{-6 \cdot 6}$
Virus + intestinal content	$10^{-2 \cdot 8}$
Virus + intestine	$10^{-2 \cdot 5}$
Virus + intestinal content and intestine	$10^{-2 \cdot 6}$

For details see text and Table 1.

they, too, had an inactivating power against *MHV*-3 virus; no effect was found.

From our results a certain ability to inactivate *MHV*-3 virus may be attributed to intestinal content and intestine of normal mice. Investigations on the mechanism of this inactivation and on the nature of the compound or compounds involved are now in progress.

Inhibition of Localized Virus Lesions by *N*-Dimethylaminosuccinamic Acid

PREVIOUS investigations have shown that the application of 2,4-dichlorophenoxyacetic acid or its salts or certain phenoxyacetic acid analogues greatly altered the number of virus lesions or the amount of virus present in tobacco ringspot (TRSV) inoculated plants[1,2]. This confirmed the findings of several other workers[3,4].

Applications of solutions containing the growth suppressant (2-chloroethyl)-trimethylammonium chloride (CCC) reduced the amount of tobacco mosaic virus in floating leaf disks[5].

This communication describes the response of tobacco ringspot virus inoculated plants of the 'SR' cultivar[6] of *Vigna sinensis* (Torner) Savi to foliar applications of the plant growth retardant chemical *N*-dimethylaminosuccinamic acid (DMAS)[7].

Seeds of the test plants were sown in 3-in. plastic pots containing two parts soil, two parts peat moss, and one part sand. In 8–10 days the primary leaves were sufficiently expanded to permit inoculation. Ten-plant plots were dusted with 400 mesh silicon carbide and inoculated with TRSV juice expressed from inoculated tobacco plants showing good symptoms of the disease. The inoculum was diluted approximately 1 : 250 with 0·01 M neutral phosphate buffer. This inoculum containing 1 per cent silicon carbide was applied by means of a 1-in.-wide, round, T-head acrylic plastic inoculator[8]. The DMAS solutions were applied approximately 45 min after inoculation when the inoculated leaves had dried. In some cases it was mixed with the inoculum. Characteristic, large, susceptible-type, localized lesions (typically preceding systemic necrosis) appeared and were counted 3–5 days after inoculation.

The results of four experiments are illustrated in Fig. 1. Application of an aqueous solution of 5,000 p.p.m. of DMAS to leaves of *Vigna sinensis* 45 min after inoculation reduced the virus local lesions by 90·1–92·9 per cent (Table 1). The solution containing 2,500 p.p.m. of DMAS was almost as effective as the stronger solution, and that containing 1,250 p.p.m. reduced lesions 66·4–83·6 per cent. Progressively less inhibition of virus lesions was caused by solutions containing 625, 312 and 156 p.p.m. of DMAS.

Table 1. INHIBITION OF TRSV LESIONS ON BLACK COWPEA (*Vigna sinensis*) BY *N*-DIMETHYLAMINOSUCCINAMIC ACID

	Exp. 1		Exp. 2		Exp. 3		Exp. 4	
DMAS (p.p.m.)	Lesion No.*	Inhibition (%)	Lesion No.	Inhibition (%)	Lesion No.	Inhibition (%)	Lesion No.	Inhibition (%)

5,000	1·4	92·4	1·7	92·9	2·1	90·1	0·0	100·0

* Means of 20 leaves.

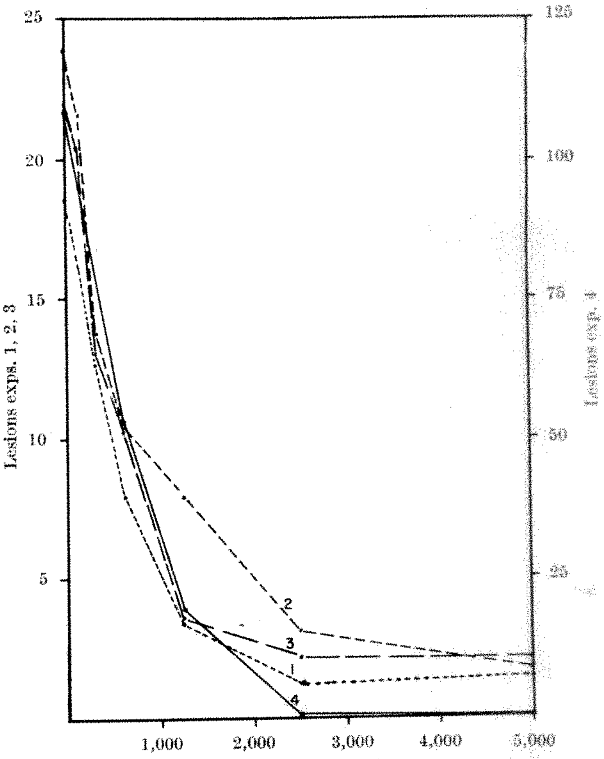

Fig. 1. Reduction of local infection of tobacco ringspot virus (TRSV). on black cowpea (*Vigna sinensis*). Foliar application of DMAS 45 min after inoculation or water spray (control, no DMAS) in exps. 1, 2, 3. Application simultaneously with inoculation (exp. 4)

Extrapolated values for zero concentration fall remarkably close to the actual values for the non-treated (water spray only) control. Lesion inhibition is consistently related to concentration of DMAS over a wide range in concentration. In some cases plants treated with solutions containing 2,500 p.p.m. or more of DMAS had irregular, small, necrotic patches. These patches probably do not represent the interference with lesion formation reported herein since they were also observed on leaves of non-inoculated plants and on non-inoculated parts of inoculated leaves. Inhibition of lesions was pronounced on many leaves with no evidence of chemical injury.

The observed response may be the result of inoculum inactivation, cell injury due to DMAS, altered host susceptibility, or viricidal action. Elucidation of the mechanism of action, however, must await the outcome of further more definitive research now in progress. Other methods and sites of application, the effects of related chemicals, and analysis of treated plants are being investigated.

PSYCHIATRY

Variations of Urinary Creatinine and its Correlation to Tryptamine Excretion in Schizophrenic Patients

In the course of investigating the effect of diet on behaviour and excretion of urinary constituents in schizophrenic patients a remarkably wide variation in the daily output of creatinine was found in several subjects. We also observed a high degree of correlation between the excretion of creatinine and urinary tryptamine. Both phenomena are shown in Fig. 1, where the daily excretions of creatinine and tryptamine along with urine volume and daily tryptophan intake are plotted over 18 consecutive days for the patient who showed the greatest association of these two variables. During the period of observation the creatinine excretion varied from 0·90 to 1·78 g/24 h with a corresponding range of tryptamine excretion of 45–182 μg/24 h. The correlation coefficients between urinary tryptamine and creatinine as well as that of tryptophan intake are presented in Table 1. Both Fig. 1 and Table 1 show that the variations of tryptamine in the urine are not related to the tryptophan intake, which was maintained between 0·53 and 1·04 g/24 h. A highly significant positive correlation is, however, associated with the excretions of tryptamine and creatinine. During the observation period, the patient received a standardized diet containing 1·0–1·5 g of tryptophan/24 h. Exact records were kept of uneaten food and the actual daily intake of each major food constituent calculated by difference. The same standardized diet was given for two months prior to the collection period in order to stabilize the tryptamine excretion in regard to tryptophan intake. No psychotropic medication had been given during 8 months previous to the experiment.

Also shown in Fig. 1 are the close relationships between the excretions of creatinine and tryptamine and the total daily urine volume. The association of urine volume with creatinine and tryptamine was observed only in this patient, while positive creatinine–tryptamine correlations were also found in other instances without large daily fluctuations in urine volume. Although it may appear that this patient was unable to concentrate urine, specific gravities ranging from 1·003 to 1·028 were found which varied inversely to urine volume. Repeated determinations of blood urea, non-protein nitrogen and serum creatinine were consistently found within normal limits. These data therefore rule out gross failures of kidney function. It may rather indicate that other humoral changes occur along with the variations of creatinine and tryptamine excretion to alter the daily urine volume.

The association of creatinine and tryptamine excretions was observed in this patient on another occasion of 16 consecutive days ($r = +0·64$) and twice in another patient for periods of 20 days each ($r = +0·56$ and $+0·33$, respectively). In addition, suggestive positive correlations were observed in a larger group of 9 patients on whom 5-day pooled urine collections were made over a 6-month period of continuously controlled tryptophan intake. For two other indole derivatives, total indolyl-3-acetic acid and 5-hydroxyindoleacetic acid, weaker but still positive correlations were obtained.

Since the classical studies by Folin[1,2] on creatinine excretion in man it has generally been accepted that the daily urinary excretion of creatinine in a given individual is quite constant and rather independent of variations of other physiological measures such as urine volume, exercise or diet[3]. Later reports, however, have indicated that considerable spontaneous variations in creatinine excretion are encountered in certain individuals[4,6]. Our findings demonstrate that the daily creatinine excretions need not remain constant but can fluctuate markedly in schizophrenic patients who are otherwise in good health and are receiving an adequate diet.

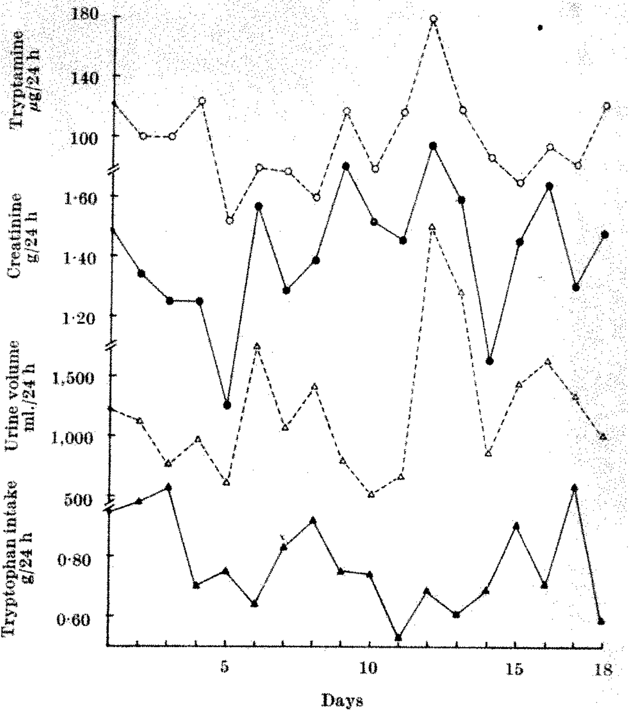

Fig. 1. Daily excretions of tryptamine, creatinine and urine volume in a schizophrenic patient for 18 consecutive days

Vestergaard and Leverett[5] have stressed the point that creatinine excretion over short periods of time should not be used to calculate excretion ratios for other urinary constituents. We should like to extend this to include the use of 24-h creatinine excretions in the case of schizophrenic patients. Numerous investigators have attempted to associate abnormalities of tryptophan metabolism with schizophrenia. Many of the reports are negative or conflicting. Some of the apparent discrepancies in the literature may be related to the fact that the creatinine excretion is usually assumed to be constant in this disease and biochemical findings are often reported as amount of substance excreted per mg or g of creatinine. Our results show that this assumption is not warranted in certain schizophrenic patients and that the excretion of tryptamine and possibly other indoles may be linked in some manner to the excretion of creatinine.

The association of tryptamine excretion with creatinine output is remarkable and may represent a metabolic finding of importance for this disease. This is indicated by the fact that the most marked daily fluctuations of creatinine and tryptamine occurred when the patient showed worsening of his psychotic symptoms, such as thought disturbances as well as delusional experiences accompanied by hyperactivity and hostility[7].

Table 1. Correlation (r) between the Daily Excretion of Tryptamine, Creatinine and Daily Tryptophan Intake

No. of daily collections	Correlation coefficient r * between urinary tryptamine † and creatinine ‡	p §	Correlation between urinary tryptamine and tryptophan intake ¶	p
18	+0·60	0·005	−0·32	n.s.

* r Correlation coefficient according to the formula by Pearson for a linear regression.

† Tryptamine was determined by the method of Sjoerdsma *et al.* (ref. 9).

‡ Creatinine was determined by the alkaline picrate method (ref. 10).

§ p is given for $t = \sqrt{\frac{r2\ (n-2).}{(1-r2)}}$

¶ Tryptophan was calculated on the basis of protein content of the food as total nitrogen.

These episodes were occasionally preceded by a reduced food intake accompanied by losses of weight. In this patient the increased creatinine output appears to be related to weight fluctuations brought about by self-imposed starvation. This observation contrasts with reports in the literature that creatinine excretion decreases during prolonged starvation in man and animals[6,8]. The possible implications of this complex clinical and biochemical pattern in relation to mechanism of periodic behavioural exacerbations in schizophrenic subjects has been discussed previously[7]. Complete details of the association of creatinine and tryptamine excretions will be reported elsewhere.

PSYCHOLOGY

Effects of Different Terminal Sounds on Short-term Memory for Initial Consonant Sounds

IF more items are presented than are to be recalled, the additional items produce a large amount of 'stimulus interference' in the recall of the remaining items[1]. This is true under conditions where subjects have complete knowledge of the items that are not to be recalled, this knowledge being possessed by the subjects before, during, and after presentation of the list. Even though subjects know which items to ignore, they cannot ignore them completely, and therefore the extra presented items interfere with the memory trace for the items to be recalled.

The purpose of the present experiment is to investigate stimulus interference in short-term recall under conditions where the number of items presented is constant, but the items in some lists contain more phonemes or 'longer' phonemes than the items in other lists. As in the previous experiment, it is important to control for response interference by holding constant the amount to be recalled. In this experiment subjects are to recall the six initial consonant phonemes of a list of six artificial items, each item consisting of a consonant followed by a vowel (CV) or a consonant followed by a vowel and another consonant (CVC). Within any one list the terminal vowel or terminal vowel and consonant are the same for each item in the list. Some of the terminal vowels and consonants are 'longer' than others in temporal duration in ordinary English speech. The experiment described here is designed to determine: (1) whether items that consist of three phonemes (CVC items) produce more stimulus interference in the recall of the initial consonant of the items than items that consist of two phonemes (CV items); (2) whether temporally longer terminal phonemes produce more stimulus interference in the recall of initial consonants than shorter terminal phonemes.

Subjects listened to a 'ready' signal, followed after 1 sec by a list of six artificial items, followed immediately by recall of the six initial consonant phonemes. Correct recall consisted of filling-in six boxes with the correct consonants in the correct order. Presentation of the artificial items was at a rate of two items/sec, and 15 sec was provided for recall. There were six conditions, each with four sub-conditions. The six conditions are six different types of lists, each type of list being a list consisting of one type of item: (SV) consonant followed by a short vowel ('a' as in father, 'e' as in let, 'i' as in bit, or 'u' as in but), (LV) consonant followed by a long vowel ('ā' as in made, 'ē' as in eat, 'ī' as in bite, or 'ō' as in hope), (SV+k) consonant followed by a short vowel followed by the short consonant 'k', (LV + k) consonant followed by a long vowel followed by the short consonant 'k', (SV + z) consonant followed by short vowel followed by the long consonant 'z', (LV + z) consonant followed by long vowel followed by the long consonant 'z'. A typical list of items in condition (SV + k) was as follows: pak, dak, gak, vak, bak, kak. The four subconditions in each condition are the four possible vowels that can be used in each condition. The order of presenting the 6 × 4 = 24 conditions was random in blocks of 24, and there were 5 blocks in the experiment, making a total of 120 experimental lists. Each experimental list contained six different initial consonants chosen from the following set of 13 consonants: b, d, f, g, k, l, m, n, p, s, t, v, z. Scattered at random through the experimental lists were 15 lists with some initial consonants appearing in more than one item in the list: 5 with one item repeated once, 5 with two items repeated once, and 5 with three items repeated once. The purpose of this was to prevent any strategy based on a belief that no initial consonant was ever repeated. Subjects were 39 M.I.T. undergraduates taking psychology courses who participated in the experiment as a part of their course requirements.

As given by Fletcher[2] the duration of the different short and long vowels and consonants is as follows: a (0·306 sec), e (0·219 sec), i (0·211 sec), u (0·280 sec), ā (0·305 sec), ē (0·341 sec), ī (not given), ō (0·325 sec), k (0·075 sec), z (0·230 sec). The average duration for these short vowels is 0·254 sec and for the long vowels is 0·324 sec. Obviously, the absolute duration of each sound depends on the rate of talking; what is important for our purpose is the relative durations of the sounds.

Scoring each item in each list as one opportunity for error yielded the ordered recall error rates for each condition that are reported in Table 1. The results are quite clear. Neither terminal vowel duration nor terminal consonant duration had any effect on recall. Increasing the number of terminal phonemes from two to three by adding a single terminal consonant consistently increased the error rate for initial consonants. The error rate for each condition was computed for each subject, and differences between any two conditions were tested using the Wilcoxon Matched-Pairs Signed-Ranks test applied to the 39 difference scores. The error rate in condition SV was significantly less than that in SV + k ($P<0{\cdot}05$) and less than that in SV+z ($P<0{\cdot}02$). The error rate in condition LV was significantly less than that in LV+k ($P<0{\cdot}001$) and less than that in LV+z($P<0{\cdot}001$). The

Table 1. ERRORS IN ORDERED RECALL OF INITIAL CONSONANTS (%)

Type of terminal	Terminal phonemes			
Vowel (V)	V	V+k	V+z	Mean
Short (SV)	41·5	44·2	45·3	43·7
Long (LV)	39·2	47·5	45·3	44·0
Mean	40·3	45·8	45·3	43·8

Table 2. 'k' AND 'z' INTRUSIONS (% OF OPPORTUNITIES FOR ERROR)

Type of intrusion	Terminal phonemes					
	SV	LV	SV+k	LV+k	SV+z	LV+z
'k'	2·3	3·2	2·6	3·1	2·7	3·5
'z'	2·7	1·4	2·2	3·3	2·5	1·6

overall difference between conditions with and without a terminal consonant was significant at well beyond the 0·001 level.

One possible explanation of the foregoing result might be that in the lists with terminal consonants the terminal 'k' or 'z' keeps 'popping into mind' during recall of the initial consonants and greatly increases the frequency of 'k' or 'z' intrusions in 'k' or 'z' lists, respectively. Table 2 shows that this is definitely not the case. The tiny increase in the rate of 'k' and 'z' intrusions from SV and LV to SV+k, LV+k, SV+z, and LV+z amounts to about 0·8 per cent, whereas the total error rate increases by about 5·2 per cent. Furthermore, the increase in 'k' and 'z' intrusions is not specific to 'k' and 'z' conditions, respectively. There is no significant difference in the 'k' or the 'z' intrusion rate between 'k' and 'z' conditions. It is clear that the stimulus interference of the terminal consonant is not reflected primarily in intrusions of that consonant.

Even though subjects know they are to ignore the terminal consonant, they cannot do so completely. The terminal consonant may weaken the memory traces for the initial consonants, or it may establish its own memory trace which competes with the traces for the initial consonants at the time of recall, or both. It is not possible to decide between these possibilities at the present time. However, it is clear that it is the presence of an extra consonant phoneme, not its temporal duration, that produces the interference.

Perception of Pattern and Colour in the Stabilized Retinal Image

OBSERVATIONS of coloured areas using the stabilized retinal image (an image which remains stationary on the retina despite eye movements) have produced reports of gradual desaturation of colours[1], or of colour fusion if bipartite coloured fields are used[2]. When black and white geometrical shapes are examined, a marked loss of contrast occurs, with ultimate failure of perception over parts or the whole of the visual field[3]. The examination of targets in which colour gradations and major pattern variations occur simultaneously has, however, not been reported; and it is not easy to predict the phenomena which might be expected to occur in these conditions.

Plates of the Ishihara test for colour blindness have been used as targets for this investigation. They were photographed as colour transparencies and viewed through two types of stabilizing apparatus; either that described by Pritchard[4], in which a miniature collimator is mounted directly on the contact lens, or through the equipment described by Clowes[5]. In this the target is viewed using a complex optical system, which, although cumbersome, permits rather more versatility in the manipulation of the target material.

In normal usage at the recommended viewing distance, Ishihara charts subtend a minimum angle of 6·5°; when viewed through the collimator they subtend 10° on a homogeneous buff background extending to 35°, and through the optical system they subtend 2° on a 10° background. In stabilized vision the targets were symmetrically disposed about the fovea and were in sharp focus. Ishihara charts provide only a crude test of colour vision, suitable for rapid screening of major defects; but they are ideally suited for the purposes of this experiment, which is to explore the gross changes of form and colour perception in stabilized vision.

Eight subjects, all of whom had previously observed black and white targets in stabilized vision, reported their subjective experiences when viewing the Ishihara charts. The following observations were made reliably and repeatedly by all subjects.

(1) In normal vision no abnormalities of colour perception were detected in any of the subjects.

(2) Fade-out of perception seemed less marked, and was certainly slower in occurring than with simple black and white material.

(3) The coloured numerals or convoluted lines desaturated and ultimately vanished as patterns, merging with a neutral-coloured background. The apparent colour of the residual image varied somewhat with the target used, and ranged from grey to dull brown or green.

(4) The background detail itself, that is, the series of tiny circles of which the target is composed, was highly stable and rarely faded out. Desaturation of colour was always more prevalent than loss of contour and the Ishihara plates often appeared as a set of uniformly bright monochromatic circles.

(5) Interruption of the light source for periods as short as 0·5 sec produced regeneration of the colours, though these quickly seemed to fade out again.

The following observations were made repeatedly by two subjects, who were the only ones to experience the experimental conditions described.

(6) Continuously flickered illumination in the frequency range 4–8 c/s (which has previously been shown to be beneficial in maintaining the visibility of a stabilized retinal image) did not prevent the colour desaturation effects described here except in the case of red lines on a grey background in which good visibility of the target and freedom from colour fusion were obtained over extended viewing periods.

(7) Side-to-side oscillation of the target through 2 min arc at frequencies in the range 4–8 c/s prevented colour fusion in targets having orange lines on a blue ground but otherwise produced no major effects.

The results of these experiments indicate that hue discrimination and form perception are mediated by separate mechanisms, for in these tests the two types of perception fail independently; disappearance of the form of the background circles was never observed to occur before colour desaturation had taken place, however.

It should be noted that failure of colour perception always produced characteristic effects which could not be confused with dichromatic vision, such as might be engendered by precise foveal fixation.

An Auditory Illusion of Distance

We have previously described experiments showing that the apparent position of a sound source in space can be moved about the horizontal plane if sound is additionally fed by a single headphone to one ear[1]; the magnitude of this apparent movement depends largely on the frequency and intensity relations between the loudspeaker and headphone sounds. As we investigated this phenomenon, which we regard as an example of binaural interaction, we noticed that if two headphones were used instead of one a single sound image was perceived the apparent distance of which from the listener could be controlled by changing loudspeaker-to-headphone loudness relations. The work recorded here examines this illusion of distance more closely.

A diagram of the experimental situation is shown in Fig. 1. A listener, wearing headphones, sat in a semi-reclining position facing a loudspeaker 320 cm away at the end of a cloth-covered arc 26 cm wide. Four red lights were spaced along the arc at a distance of 320, 250, 150 and 50 cm from the listener's head. Ten msec bursts of band-pass filtered noise (1·5–6 kc/s) were delivered at a repetition rate of 6 per sec to both loudspeaker and headphones. The headphone stimulus was delayed electronically so that the speaker and headphone pulses would reach the listener simultaneously.

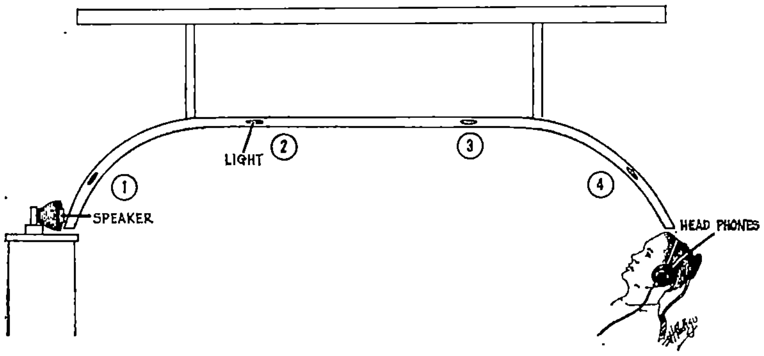

Fig. 1. Diagram of listening situation showing relation between loud-speaker, light positions Nos. 1–4 and listener

Six listeners participated. The tests were conducted in a sound-treated room the only illumination of which was that provided by the lights mounted on the arc. Headphones were placed on the listener and thresholds were then determined for the speaker and for the headphone stimuli. Next, with the speaker stimulus presented at 15, 20 or 25 db above threshold, the listener was instructed to adjust an attenuator controlling the headphone stimulus (2 db steps) until the perceived auditory image was coincident with a previously specified light. As soon as the listener had accomplished this, his attenuator reading was recorded. The listener was then asked to bring the sound image to coincide with a different light and the new attenuator reading was recorded. This scaling procedure was repeated six times, and median attenuator settings were calculated for each of the four lights at each of the three sensation-levels of the speaker stimulus.

To recapitulate: in this first or scaling session the listener was given control over one of the attenuators and was asked to adjust it so as to move the sound image to particular locations. In the next five sessions the listener had no control over the stimuli; the attenuator settings he had previously arrived at were reproduced and he was asked to identify the light positions from which the sounds appeared to be originating. As soon as he responded the 'correct light' was brightened briefly to tell him whether his choice was consistent with judgements made during his scaling session. Listeners were given six trials per session with each of the twelve possible combinations of speaker/headphone sensation-levels. Order of presentation was varied from day to day.

Table 1. MEDIAN PER CENT CORRECT IDENTIFICATIONS OF ILLUSORY AND REAL DISTANCES

	Light positions			
Distances	1	2	3	4
Illusory	84	77	85	97
Real	48	55	81	88

Table 1 shows the median per cent 'correct' identifications for all test sessions. No significant improvement in performance could be detected as testing progressed, suggesting that listeners were not learning to recognize apparent sound sources on the basis of any qualitative differences between sounds. Several persons who took no part in these formal tests nevertheless listened to the stimulus combinations; nearly all volunteered that the distance illusion was striking.

We were interested in finding out how well a listener would perform if the sound was actually emanating from one or the other light position; in other words, using 'real' rather than 'illusory' distance. Five additional sessions were conducted with a small loudspeaker placed next to each light. No headphones were worn on these occasions. Thresholds were taken for the loudspeaker at light position No. 1 and the auditory stimuli delivered by each of the speakers was set to 15, 20, or 25 db above this threshold. Median per cent 'correct' identifications for this condition are also shown in Table 1. A comparison of these figures with those obtained earlier clearly shows that over-all performances were superior when listeners were asked to judge illusory rather than real distances.

When other cues for distance are minimal, a listener judges the distance of a sound primarily by its loudness; that which is louder appears nearer[2]. Our listeners performed poorly in judging real distances presumably because there was an overlap of loudness between adjacent speakers and hence the loudness cues were ambiguous. There was also loudness overlap between many of the combination stimuli used in the illusory distance test; but listeners performed reliably and were able, in the majority of instances, to identify illusory distance correctly. In fact, the illusion of distance can be compelling even when the normal loudness cues are reversed ; thus we have observed that as the intensity of the loudspeaker is increased (increasing the total perceived loudness) a sound image previously located in the head can be moved away. These observations indicate that whatever the basis for this illusion of distance it certainly concerns more than loudness. In the experiments so far described the intensities at the two ears have been equal; however, if a right-left intensity differential is introduced and suitably varied, the apparent sound source in space now moves laterally.

In these types of listening situations, the two auditory inputs (loudspeaker and headphones) each acting alone produce an auditory image; one is externalized while the other appears to be in the head. When the two inputs are presented simultaneously only a single image is perceived. Our results suggest that the apparent location of this fused image is determined by the relative dominance of the two separate images.

MATHEMATICS

Gravitational Collapse

In a recent letter[1] Prof. H. Bondi states that it is impossible to determine the number of particles contained in a static distribution of matter and radiation by means of an integral over that configuration. In so doing he denies to a local observer the capability of measuring the number of particles contained in a small but finite volume, and thereby denies the possibility of assigning a physically meaningful particle density at every point in the configuration.

If, on the other hand, one asserts that an observer can determine a local number density, it is easy to show that the total particle content of any configuration is a well-defined invariant quantity.

The infinitesimal integral:

$$\int_{\Delta} \sqrt{-g}\, \mathrm{d}x^1\, \mathrm{d}x^2\, \mathrm{d}x^3\, \mathrm{d}x^4$$

is a known invariant[2]. It is always possible to choose the co-ordinate system in such a way that $g_{\mu 4} = g_{4\mu} = \delta_{4\mu}$. Hence:

$$\int_{\Delta'} A^4 \sqrt{-g}\, \mathrm{d}x^1\, \mathrm{d}x^2\, \mathrm{d}x^3$$

where A^4 is the fourth component of an arbitrary vector, is also an invariant. In a local Cartesian frame of reference, $g_{11} = g_{22} = g_{33} = -1$, $g_{44} = 1$ and $\mathrm{d}x^1\, \mathrm{d}x^2\, \mathrm{d}x^3$ represents an infinitesimal proper volume element. If A^4 is chosen as the local proper particle density, q, then:

$$\mathrm{d}N = \int_{\Delta'} q\, \mathrm{d}x^1\, \mathrm{d}x^2\, \mathrm{d}x^3$$

represents the invariant number of particles contained in the chosen volume element. Transforming to a co-ordinate system commonly used for spherically symmetric systems:[3]

$$(A^4)' = \frac{\partial(x^4)'}{\partial x^{\nu}}\, A^{\nu} = \frac{\partial(x^4)'}{\partial x^4}\, A^4$$

$$= e^{-\nu/2}\, q$$

$$\sqrt{-g} = e^{\nu/2}\, e^{\lambda/2}\, r^2 \sin\theta$$

and, finally:

$$N = \int_{\text{entire system}} q\, e^{\lambda/2}\, r^2 \sin\theta\, \mathrm{d}\theta\, \mathrm{d}\varphi\, \mathrm{d}r$$

gives the total invariant particle content of the system.

In this same co-ordinate system:

$$M = \int_{\text{entire system}} \rho\, r^2\, \mathrm{d}r \sin\theta\, \mathrm{d}\theta\, \mathrm{d}\varphi$$

where ρ is the proper energy density, represents the total gravitational mass of the system. It is clear that N and M are linearly independent unless very stringent and non-physical limitations are placed on the relationship between the particle density, energy density, and pressure distributions.

The particular choice of q (as well as of ρ and pressure), which has physical meaning, must, of course, involve further considerations. If the static configurations are to represent stages in the evolution of a real body losing energy, then considerations of energy flow within the body place restrictions on the relation between the pressure and temperature distributions which, in addition to a physically reasonable choice of equation of state, serve to specify uniquely the relation between the ρ, q, and pressure distributions at different stages in the evolution of the system.

Bondi appears to confuse the meaning of indistinguishability owing perhaps to his failure to recognize the distinction between energy density and particle density. Two static configurations with identical energy density and pressure distributions may certainly contain different numbers of particles, as Bondi himself states. But if we can attribute different nucleonic content to the two configurations, we have clearly distinguished them from one another, despite the fact that they may possess the same gravitational mass (that is, total energy content).

In the example which Bondi cites, the two systems initially have total mass $M_1(0)$ and $M_2(0)$ and particle number $N_1(0)$ and $N_2(0)$. Let m_1 and m_2 represent the rest masses of particles contained in 1 and 2. Since, in the chosen initial states, energy density and (particle-mass × particle-density) are identical, $m_1 N_1(0) = M_1(0)$ and $m_2 N_2(0) = M_2(0)$. Bondi demands that, after a time t, $M_1(t) = M_2(t)$, $M_1(t) = M_1(0)$, and $M_2(t) < M_2(0)$. In so doing he has simply assigned different physical properties to the matter-radiation field in the two cases. His particular choice of the relationship between energy density, pressure and particle density is such that, since $M_2(0) > M_1(0)$, $N_2(t) m_2 = N_2(0) m_2 > N_1(t) m_1 = N_1(0) m_1$. This conclusion, to which Bondi also subscribes, does not demonstrate the impossibility of determining particle number from a relativistic integral over a static configuration; on the contrary, it is reached only by considerations, implicit or otherwise, based on the existence of such an integral.

I am afraid Dr. Iben and I have been misunderstanding each other. In my communication I pointed out that an integral involving only the density and pressure of the material could not reveal the particle number. I correctly referred to a contrary statement by Eddington; but I mistakenly also referred to Dr. Iben's paper, which I had misunderstood. I now appreciate that no such error does in fact occur in his paper. On the other hand, Dr. Iben has misunderstood my communication. I stressed at the beginning that I was discussing integrals involving only the density and pressure of the material, and used the words 'relativistic integral' further on merely as a shorthand for this. In particular, I was thinking of Eddington's identification of the energy invariant as particle number density.

I trust that Dr. Iben agrees fully with me that no term or combination of terms of the energy tensor has any connexion with the particle number. The particle number may be put into the theory as is done in Dr. Iben's own work, but in no way can it be deduced from the metric.

H. BONDI

King's College
(University of London),
Strand, W.C.2.

I agree with Prof. Bondi that only energy density and pressure are included explicitly in the energy tensor. However, both energy density and pressure are related to particle density and any application of relativistic theory to a physically realistic description of a massive body in a highly condensed state requires a choice as to this relationship.

FORTHCOMING EVENTS

Wednesday, September 16

Bone and Tooth Society (at the Royal National Orthopaedic Hospital, 34 Great Portland Street, London, W.1), at 4.30 p.m.—Annual General Meeting followed by Casual Communications.

Royal Aeronautical Society, Graduates' and Students' Section at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Film Show.

Thursday, September 17

Mineralogical Society (in the Geology Department of Bristol University, Queen's Building, University Walk, Bristol), at 2.30 p.m.—Scientific Papers.

Institution of Mining and Metallurgy (at the Geological Society' Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. W. Fletcher, Dr. D. S. Flett and Mr. J. C. Wilson: "Solvent Extraction of Ferric Iron by a Carboxylic Acid"; Mr. R. Healey and Mr. V. E. Clifton: "Some Recent Developments in the Construction of Vertical Zinc Retorts at Avonmouth".

Friday, September 18

Association of Clinical Biochemists, South Region (at the Middlesex Hospital Medical School, London, W.1), at 7 p.m.—Discussion Meeting on 'Hospital Laboratories in Denmark and Sweden". Speakers: Mr. P. M. G. Broughton, Dr. A. B. Anderson and Dr. Clifford Riley.

Television Society (in the Conference Suite, I.T.A., 70 Brompton Road, London, S.W.3), at 7 p.m.—Mr. E. J. Gargini: "Colour Television by Wire".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer or Lecturer in Soil Science in the Department of Crop Husbandry and Horticulture, University of Ghana—The Assistant Registrar, University of Ghana Overseas Office, 15 Gordon Square, London, W.C.1 (September 15).

Assistant Lecturer or Demonstrator (with medical qualifications registrable in the United Kingdom) in Anatomy—The Registrar, The University, Manchester 13 (September 19).

Lecturer or Assistant Lecturer (preferably with an interest and research experience in electrical and magnetic ceramics) in Ceramics, in the Division of Ceramics, Houldsworth School of Applied Science—The Registrar, The University, Leeds, 2 (September 19).

Chair in Brewing and Applied Biochemistry; and Chair in Civil Engineering—The Principal, Heriot-Watt College, Edinburgh (September 21).

Research Assistant (honours graduate in zoology, biochemistry or genetics) in Genetics, to participate in investigations into the physiological genetics of melanotic tumours in the fruit-fly *Drosophila*—The Registrar, The University, Leeds 2 (September 21).

Research Assistant in the Department of Geography—The Registrar, The University, Leeds, 2 (September 21).

Senior Lecturer in Education; a Senior Lecturer in Physics; Lecturers (2) in Chemistry; a Lecturer in Education, a Lecturer in Electrical Engineering; a Lecturer in Geography; a Lecturer in Physics; a Lecturer in Psychology; and Lecturers (2) in Zoology at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 21).

Special Research Assistant to Professor M. M. Cole in the Department of Geography—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (September 21).

Chair of Mathematical Economics or Econometrics—The Registrar, The University of Warwick, Coventry (September 25).

Chair of Psychology in the Faculty of Science—The Registrar, University of Birmingham, Birmingham 15 (September 25).

Veterinary Surgeon (man or woman aged 35 or over, M.R.C.V.S., with considerable professional experience, including experience of care of laboratory animals) in London, for duties which include inspection of premises registered for experiments, and advising on applications for licences or certificates—The Civil Service Commission, Savile Row, London, W.1, quoting Ref. 5956/64 (September 25).

Lecturer or Assistant Lecturer (with a good honours degree in chemistry or pharmacy) in Pharmacy—The Registrar, The University, Manchester, 13 (September 26).

Reader in Microbial Genetics—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (September 26).

Research Fellow or Assistant in Psychology at Queen's College, Dundee, to work on a research project on the bisensory presentation of information—The Secretary, University of St. Andrews, Queen's College, Dundee, Scotland (September 26).

Assistant Curator (with a degree and experience in medieval and later archæology, including excavation supervision) in Archaeology—The Director, City Museum, Bristol (September 28).

Scientific Officer (with a first- or good second-class honours degree in physics, or alternatively in engineering, and preferably some research experience in a branch of classical physics)—The Director, Agricultural Research Council Unit of Soil Physics, School of Agriculture, The University, Cambridge (September 28).

Pfizer Research Fellow for work in the Department of Pharmacy under the direction of Prof. J. B. Stenlake on the metabolism of drugs—The Registrar, The University of Strathclyde, George Street, Glasgow, C.1 (September 30).

Lecturer in Oral Pathology in the School of Dental Surgery—The Registrar, The University, Liverpool, quoting Ref. CV/261 (October 3).

Technical Officer (with a university degree or an equivalent technical qualification) in the Computing Laboratory, Department of Mathematics, Queen's College—The Secretary, University of St. Andrews, Queen's College, Dundee, Scotland (October 3).

Assistant Lecturer (with an honours degree in sociology) in Sociology at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 5).

Lecturer or Assistant Lecturer in the Biochemistry Department, University of the West Indies—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (October 5).

Assistant Lecturer in the Chemistry Department—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.C.1 (October 9).

Chair of Electrical Engineering—The Secretary, The Queen's University, Belfast, Northern Ireland (October 10).

Lecturer (graduate in science or medicine) in Pharmacology at the University of Western Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 10).

Senior Lecturer or Lecturer (preferably with interest in morphology or physiology) in Botany at Ahmadu Bello University, Northern Nigeria—The Secretary Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 10).

Reader in Medical Physics at the Postgraduate Medical School of London—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 12).

Senior Lecturer in Mathematics at the University of Western Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 17).

Chair of Numerical Analysis—The Registrar, The University, Liverpool (October 30).

Laboratory Steward in the Department of Physics, The Victoria University of Wellington, New Zealand, to be responsible for the general care and efficient operation of the laboratories and equipment—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (November 6).

Adviser (honours graduate between 30 and 50, national of the United Kingdom or the Republic of Ireland, with experience in cocoa research, genetics, breeding and agronomy) on Cocoa Research, Colombia, to be responsible for cacao research with special regard to obtaining improved varieties or hybrids, and efficient methods of cultivation—Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/43/02.

Agronomist (with a degree in agriculture, and preferably field experimental experience) in Swaziland, to conduct field experimentation into soil fertility and fertiliser problems—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC213/169/07.

Animal Husbandry Officer (national of the United Kingdom or the Republic of Ireland, with a degree in agriculture, and extensive experience in practical animal husbandry, preferably with tropical livestock) in Sarawak, to develop the livestock industry—The Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/155/06.

Assistant Lecturer or Lecturer in Experimental Physics—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex, marking envelope "Application".

Biochemist, Basic Grade (graduate in chemistry, biochemistry, chemistry with physiology or biology or Grad.R.I.C.) for the Biochemistry Section of the Pathology Department—The Secretary, Hope Hospital, Salford, 6.

Biochemist (with interest in the central nervous system) for work on biochemical and electron cytochemical aspects of demyelinating diseases—The Director, M.R.C. Research Group of Demyelinating Diseases, 13 Framlington Place, Newcastle upon Tyne, 2.

Chair of Plasma Physics—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex, marking envelope "Confidential".

Field Assistant (with a degree in zoology, or zoology and botany, a strong interest in ecology and conservation, and fit enough for continuous field work)—The Warden, Slapton Ley Field Centre, Slapton, Kingsbridge, Devon.

Isotope Technician to join a team engaged in investigating and treating thyroid disorders with radioactive iodine—The Hospital Secretary, New End Hospital, London, N.W.3.

Junior Research Associate (with a good physics honours degree) in Physics, for research work on microwave resonance in semiconductors to be carried out under the direction of Dr. E. E. Schneider, Reader in Solid State Physics—The Registrar, The University, Newcastle upon Tyne, 1.

Laboratory Technician for work in the medical application of radioactive isotopes—The Secretary, Institute of Nuclear Medicine, Middlesex Hospital Medical School, London, W.1.

Mathematician to teach mathematics to all levels—The High Master, Manchester Grammar School, Manchester, 13.

Microbiologist (with at least a B.Sc. degree with microbiology as a major subject or the equivalent, and several years experience) in the Microbiological Section of the South African Bureau of Standards, Pretoria, to assist in an actively developing microbiological section, whose functions are concerned mainly with industrial microbiology, for example, testing of germicides, food products, antibiotic potencies, maintenance of stock cultures, conducting microbiological factory surveys of food processing plants, etc.—The Attaché (SABM), South African Embassy, South Africa House, Trafalgar Square, London, W.C.2.

Medical Laboratory Technician (A.I.M.L.T. or equivalent); and a Scientific Officer (with a science degree) for interesting work of a specialist nature—The Administrative Officer, North London Blood Transfusion Centre, Deansbrook Road, Edgware, Middlesex.

Physicist, Basic Grade (with a good degree) for the Physics Laboratory—The Secretary, Lambeth Hospital, Brook Drive, London, S.E.11.

Reader (preferably with a higher degree and actively engaged in research in fluid mechanics and thermodynamics) in the Department of Aeronautical and Mechanical Engineering—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST 64/90.

Research Assistant (with a good honours degree or diploma in archæology) in Archæology at the University of Ibadan, Nigeria, to assist the Research Prof. of Archæology—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

Research Assistant for an investigation involving histochemistry and tissue culture—The Secretary, Pathology Department, St. George's Hospital Medical School, London, S.W.1.

Research Assistants (2) (science graduates) in the Department of Histology and Electron Microscopy—The School Secretary, Royal Dental Hospital of London, School of Dental Surgery, Leicester Square, London, W.C.2.

Research Student for the development of new techniques in stress determination by use of brittle lacquer and strain gauging—Prof. W. A. Tuplin, Applied Mechanics Department, The University, Sheffield.

Research Students in Organic and Organometallic Chemistry—The Professor of Chemistry, University of Sussex, Brighton, Sussex.

Scientific Officer (young graduate physicist or physical chemist, preferably with two or three years research experience) in the Physics Laboratory, for work concerned with the application of physical measurements to baking problems—The Secretary, British Baking Industries Research Association, Baking Research Station, Chorleywood, Rickmansworth, Hertfordshire.

Senior Physicist (Senior Grade); and an Assistant Physicist (Basic Grade) in the County Medical Physics Department, St. George's Hospital, Lincoln—The Group Secretary, Lincoln No. 1 Hospital Management Committee, County Hospital, Sewell Road, Lincoln.

Senior Physicist to be in charge of a group concerned with the application of electronics in medicine—The Chief Physicist, Regional Medical Physics Department, Sheffield Regional Hospital Board, 21 Claremont Crescent, Sheffield, 10.

Senior Technician I (with experience in biochemistry) to work under the direction of the Biochemist—The Consultant Pathologist, Hereford County Hospital, Hereford.

Senior Technician (with good general histological experience and appropriate qualifications) to take charge of a histological research laboratory —Dr. W. P. Dallas Ross, The Medical School, The University, Birmingham, 15.

Technician for clinical research in the Respiratory Function Laboratory —The Assistant Secretary, University College Hospital, Gower Street, London, W.C.1.

Veterinary Officers (male, M.R.C.V.S. or equivalent) in Northern Rhodesia, for general veterinary work, including control and prevention of livestock disease, supervision of vaccination campaigns and mass treatments —The Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 217/132/02.

BRITAIN'S CONTRIBUTION TO EDUCATION OVERSEAS

FOLLOWING the memorandum relating to the Commonwealth Education Conference meeting at Ottawa during August–September, issued in June by the Council for Education in the Commonwealth, Political and Economic Planning has published a valuable broadsheet, *Teachers for the Commonwealth—the British Contribution**. That contribution is appraised and criticized in the light of the wider context of education in the developing countries generally. Written by M. Elphick and R. Manley, the Broadsheet, like Mr. Guy Hunter's *Education for a Developing Region* (see *Nature*, 203, 677 ; 1964), centres largely on a study of East African problems. In this case, however, the research on which it is based was concerned with East African students in Britain. Both studies were assisted by grants from the Ford Foundation, and, like Mr. Hunter in his introduction and that part of the book which discusses policy issues, the Broadsheet illumines the way in which Commonwealth problems are related to wider issues and emphasizes the real dangers and difficulties which confront African Governments to-day in dealing with educational issues.

It is somewhat curious, therefore, that neither Mr. Hunter nor the Broadsheet refers to Dr. S. Dedijer's percipient article "Underdeveloped Science in Underdeveloped Countries", published in *Minerva* last autumn (see *Nature*, 201, 1153 ; 1964). Both seek, within the specific but scarcely more limited field of education, to stress the basis of education policy, the dangers which the Governments of developing countries should seek to avoid, and the points to which countries providing educational assistance should give particular care and attention. The memorandum from the Council for Education in the Commonwealth was particularly concerned that full use should be made of the opportunity afforded by the Ottawa Conference and that principles underlying the existing schemes for Commonwealth exchanges of teachers and students should be viewed in their wider context and also in relation to such questions as: (1) whether the training given in Britain and other advanced countries actually constitutes a serious drain on the developing countries because their scholars never return; (2) whether their own universities and postgraduate schools are losing their best talent; (3) whether the courses for overseas students are designed to make the maximum contribution to the economic and social development of these countries. The form in which educational aid can most usefully be given calls for consideration, as well as the manner in which liaison should be achieved between Commonwealth programmes and those of international organizations, like Unesco, which are attempting to co-ordinate educational development in the developing countries as a whole.

The Commonwealth Prime Ministers' Meeting in July took note of the scope which exists for co-operation between the Governments and peoples of the Commonwealth in social as well as economic development. It expressed warm wishes for the success of the Ottawa Conference and made known its appreciation of the British Government's offer to increase to an average of £5 million a year, over the 5 years starting in 1955-56, the capital assistance which it already provides for higher education in developing Commonwealth countries. However, the communiqué issued by the Meeting on July 15 did not reflect the imagination for which the Council for Education in the Commonwealth is looking, nor did the debate on the communiqué in the House of Lords on July 29—though the significance of Voluntary Service Overseas was recognized by the Bishop of Chester and the Duke of Devonshire. In all fairness, it should be noted that the communiqué refers to the Prime Ministers' belief that it might be valuable to supplement the existing arrangements for promoting the study of administration and development planning throughout the Commonwealth. It should also be recorded that the Prime Ministers considered that there might be advantages in making arrangements which could include the formation of a new institute to provide facilities for specialized training and research for senior administrators concerned with development problems in relation to the needs of new countries. Moreover, they agreed that arrangements for additional training should include the strengthening of existing institutions. The context of this section of the communiqué indicates that to some extent the Prime Ministers were aware of the implications of Dr. Dedijer's argument about the planning and execution of development projects. The reference to the desirability of establishing a Commonwealth Foundation to increase interchange between Commonwealth organizations in professional fields certainly shows some imagination, but it may well require more generous contributions from Commonwealth Governments than is visualized in the communiqué, and support from both public and private quarters may also be desirable.

At Ottawa this year the agenda included three new items for discussion : adult illiteracy ; mass media ; and co-operative arrangements for the planning and development of educational institutes. These were welcomed by the Council for Education in the Commonwealth, though its memorandum, in the main, is limited to reviewing the existing schemes. It urges the need for some shift in emphasis in co-operation towards building up institutions in the developing countries of the Commonwealth. The representations of the Council in this memorandum generally follow the pattern of the report on the second Commonwealth Education Conference at Dublin. The Council urges that under the Commonwealth Scholarship and Fellowship Plan there should be a substantial programme of new awards, particularly in professional and technical subjects, and emphasizes the importance of more students from Britain and the other advanced countries taking up the scholarships now being offered in the developing countries. It is seriously concerned over the training of teachers. Because only about 3 per cent of overseas students in Britain are training to be teachers, it is also concerned to ensure that the teachers when trained return home to serve as teachers in their own countries. The justification for the whole Commonwealth bursary scheme would largely disappear if a high proportion of those being trained as teachers took up other jobs on their return home. The Council also suggests that the Commonwealth Education Liaison Committee should supply an annual report on training awards similar to that provided by the Commonwealth Scholarship and Fellowship Plan, and it recommends co-operative Commonwealth planning for developing teacher training institutions in the developing countries, especially in finding staff.

---

* *Planning*, 30, No. 482 (August 17, 1964). *Teachers for the Commonwealth—the British Contribution.* By Michael Elphick and Roy Manley. Pp. 243–282. (London: Political and Economic Planning, 1964.) 5s.

Another important recommendation is that the Conference should, in future, re-assess the long-term needs of the developing countries and propose plans for satisfying these needs. It is in this connexion that the memorandum refers to Unesco projects such as the Addis Ababa Plan, which revealed future needs far beyond those discussed at the first two Commonwealth Education Conferences. Only in such a context is it reasonable to expect that recruitment difficulties will be minimized, if not eliminated, and the foundations laid for a career service mutually satisfactory to the teacher and the developing country. It would also help to disclose the attitude of the developing countries to any fresh proposals for the development of a non-Commonwealth career service as visualized by Political and Economic Planning. The memorandum also recommends that the Conference should consider how the establishment of regional English language centres, as recommended at Delhi, could be accelerated, and the Council is even more concerned about the poor response to Britain's offer of bursaries for overseas students training to become technical teachers. This, and difficulties in the way of obtaining industrial experience, call for investigation both by the Conference and by the British Government.

Other recommendations addressed to the Ottawa Conference are concerned with the place of Governments and voluntary bodies in social education and the place of social education in Commonwealth co-operation. The British Government is asked to consider, in consultation with British publishers, how best to help establish indigenous publishers, printers and booksellers in the developing Commonwealth countries where they do not already exist. It is also asked to look into ways of giving financial assistance to voluntary organizations in Britain which help with training programmes for Commonwealth countries in university education. Clearly, too, the Commonwealth Education Liaison Committee can scarcely be expected to undertake the new duties envisaged in the memorandum, or even to implement really effectively those placed on it by the Delhi Conference, unless it is more adequately staffed and financed, with wider terms of reference.

This is recognized by the Council for Education in the Commonwealth, and the appropriate action recommended in its memorandum is in line with the concern of the Prime Ministers' Conference to strengthen a Commonwealth Secretariat, and with the criticism that the complexity and diversity of Britain's present administrative structure is a hindrance to educational co-operation which is expressed in the Broadsheet from Political and Economic Planning. Equally in line with the findings in that Broadsheet is the conclusion, in the Council's memorandum, that the main gap in Britain's present financial arrangements is the lack of regular provision to help independent Commonwealth countries in building up their institutions. Moreover, the funds devoted specifically to schemes of Commonwealth educational co-operation at Oxford and Delhi have not been large, and a substantial part of Britain's own allocation of £6 million is unlikely to have been spent by 1965; actual money transfers for educational purposes have not been made under the Commonwealth Educational Co-operation arrangements.

The Broadsheet is concerned essentially with only one aspect of educational co-operation—that of the British contribution to training teachers. However, it derives much of its value from the way in which Commonwealth co-operation in this field is seen in the light of the three massive Unesco plans for educational development, in Asia (the Karachi Plan of 1960), in Africa (the Addis Ababa Plan of 1961, followed by the Tananarive Conference in 1962, dealing with higher education, for which Sir Alexander Carr-Saunders directed a study *Staffing African Universities* †) and in South America (the Santiago Plan of 1962). All three of these plans stress the necessity for co-ordination and planning, both in general educational development and in the provision and acceptance of external assistance. A meeting in Tokyo in 1962, following up the Karachi Conference, also asked for a substantial increase in external assistance. A White Paper on the progress of the Department of Technical Co-operation, in 1962, stressed the importance of international co-ordination, and the Chairman of the Development Assistance Committee of the Organization for Economic Co-operation and Development emphasized the increasing complexity of the flow of assistance to developing countries.

Britain's contribution to educational assistance has recently been described independently in a survey by Peter Williams for the Overseas Development Institute (see *Nature*, 203, 439 ; 1964) and it is unnecessary here to recapitulate the detail, but Mr. Williams's reflexions anticipate some of the comments and conclusions of the Broadsheet. Although developing countries all over the world are gravely short of teachers, the Broadsheet recognizes that it is logical that Britain's help should go mainly to the Commonwealth, within the framework of a wider international effort. This is especially so since the Commonwealth has a special place in Britain's educational technical assistance and the member countries share a common administrative background and educational history and are in a particularly favourable position to help each other. It is recognized, too, that Britain's administrative arrangements in this field are necessarily affected by her present educational structure, and the consequent voluntary nature of the procedure in recruiting teachers with a constant emphasis on short-term secondments. Further, these circumstances have led to grave problems in the receiving countries and in the recruiting agencies. These problems, impeding harmonious and efficient co-operation, have lowered Britain's ability to supply enough teachers to meet the demand.

The Broadsheet makes three main criticisms of Britain's contribution: it is *ad hoc* and short-term in nature; attempts at long-term planning seem to have been neglected, and executive procedures in recruitment need simplifying. Another impediment lies in the belief that the future demand is unlikely to be sustained, and a third is the shortage of teachers at all levels in Britain and the consequent reluctance of universities, and of local education authorities, which have a statutory obligation to provide adequate educational services in their areas, to make matters worse for themselves by sending their teachers overseas.

---

† *Staffing African Universities*. By Sir Alexander Carr-Saunders. Pp. 26. (London: The Overseas Development Institute, 160 Piccadilly, W.1, 1963.) 2*s*. 6*d*. See also *Nature*, 198, 1024 (1963).

An obvious first step, as the Council for Education in the Commonwealth recognizes, is to obtain more accurate estimates of future needs for teachers. Countries such as Nigeria and Tanganyika are already beginning to attempt such forecasts, and Britain could help by building up her technical and advisory staff in the overseas High Commissions and by a greater emphasis on detailed planning on the spot. To meet requirements over a long period, however, calls for an all-out planned effort by British agencies and for co-ordination by the Government, whether through the present Department of Technical Co-operation and the Foreign, Colonial and Commonwealth Relations Offices, or through a Ministry of Overseas Development, as envisaged by the Labour Party. In any event, the Government must revise its entire approach to technical assistance in education, and must recognize that long-term demands, as well as more immediate needs, have to be met.

The Broadsheet stresses the importance of securing the closer co-operation of the various bodies interested in this field. It recommends that the Commonwealth Education Liaison Committee and its Unit should be strengthened and its authority increased as an instrument for channelling education assistance to Commonwealth countries in collaboration with international agencies and with other donor countries. Beyond this the Broadsheet criticizes the Department of Technical Co-operation for rejecting the recommendation of the Select Committee on Estimates for the establishment of a Commonwealth Advisory and Technical Service, based on a pool of officers in the permanent employ of Britain and seconded to overseas Governments. On the contrary, it finds powerful arguments for a small Commonwealth Education Service, which the authors of the Broadsheet believe would attract teachers of high calibre. The demand would guarantee employment for its members in a variety of posts for a long time to come, and the periods spent in Britain between postings would provide opportunities for professional refreshment through secondment to local education authorities, schools, colleges and universities. The Service could have its own internal structure and its members could be assured of increasing emoluments, with prospect of eventual absorption into the administrative and educational offices of the Ministry or into Britain's teaching service. The Broadsheet questions whether a supply of teachers from Britain can be guaranteed, unless there is a regular service from which teachers can be posted, and it recommends that the Government should urgently consider forming such a Commonwealth Education Service. In the meantime, the Government should materially encourage education authorities at all levels to be fully aware of the part which they can play in Britain's contribution to Commonwealth education.

Mr. Williams's survey of educational assistance for the Overseas Development Institute convinced him also that Britain's administrative arrangements were too complicated and that her aid was not always deployed to the best advantage. While specifically recommending the setting up of a Commonwealth Educational Service, he does not suggest that all decisions and making of policy could be concentrated in a single functional department. He, too, emphasizes the need for fresh and imaginative thinking on administration and finance by the Government—this should not be a matter of party politics. This is also underlined by Mr. Guy Hunter, who is at some pains to stress not merely the opportunities of educational aid and the vital importance for Britain herself that she should take a full part in this work, but also the way her capacity to participate is affected by the structure and character of her own educational institutions. His preoccupation with East Africa does not lead him to overlook the needs of Africa and Asia generally.

All these appraisals of Britain's effort in educational assistance and of the opportunities which confronted the Ottawa Conference are fair and well balanced, nor do they forget that education is only one aspect of technical assistance, though perhaps the most vital. Nevertheless, those other aspects sometimes require special consideration in the context of education, and alone among the surveys mentioned here Sir Alexander Carr-Saunders's paper touches on the question of research. This is a factor which can be as important in attracting university teachers from Britain to teach in overseas institutions as promoting the development of flourishing academic institutions in the developing countries. Here Britain has much to give and there has so far been lamentably little evidence that the British Government is alive to the opportunities or the importance of the issues. The decision to dissolve the Overseas Research Council is only the latest evidence of an indifference that verges on folly. It would seem probable that the Government's attitude is responsible for so few scholarships offered in developing countries being taken up at present from Britain. Moreover, this accusation could well be levelled at other developed Commonwealth countries. No Commonwealth Educational Service which covers university teachers should be allowed to neglect the relation between teaching and research. It is to be hoped that some searching enquiries will be brought to bear in the near future on research opportunities overseas, especially on the functioning of the Commonwealth Scholarship and Fellowship Plan and the supply of teachers overseas.

FUEL CELLS

Fuel Cells

Edited by Will Mitchell, jun. (Chemical Technology: a Series of Monographs, Vol. 1.) Pp. xv + 442. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 107*s.* 6*d.*

For more than a hundred years a practical solution to the problem of obtaining electrical energy directly from oxidizable fuels has been the subject of many enquiries. These have, of recent years, become more active under the stimulus of various national interests, and the problems which have to be solved before a satisfactory economic 'fuel' cell can be constructed have in consequence become more clearly defined.

It is fitting that the important subject should be dealt with in the first volume of a new series of monographs on *Chemical Technology*, and Mr. Will Mitchell, jun., is to be congratulated on his success in collecting together the views and work of no less than fifteen of the more active workers in this field, nearly all being citizens of the United States. There is included, however, a good deal of the work of the committee on fuel cells of the English Electrical Research Association, for the investigations of this committee included not only the hydrogen oxygen cell which culminated in the development of porous electrodes and the Bacon cell, but also the fused salt hydrocarbon air cell made operative at Sondes Place by the utilization of effective silver zinc electrodes as well as suitable membranes and eutectic salt mixtures. In addition, less successful cells were developed on the utilization of Nernst type solid electrolytes at Birmingham and oxy-redox cells, some of which showed promise, in London.

While the electronic mechanism of a hydrogen electrode is now well understood, the mechanism of ensuring a high rate of transfer of gaseous hydrogen to the chemisorbed state at the catalytic electrode electrolyte interface so as to ensure a high current density is not readily solved while the oxygen electrode mechanism is still a matter of controversy. The relatively high cost of hydrogen renders the hydrocarbon and particularly the carbon monoxide cell especially attractive, and it may be that a technical battery along these lines may be the ultimate solution.

The book contains a wealth of information which will save future investigators much labour. It suffers, one supposes, unavoidably by the fact that as each chapter is written by a different author, there is a great deal of repetition both in historical as well as theoretical material. This is compensated for in part at least by the somewhat different points of view adopted. It is said that an ill wind blows nobody any good, but the interest in the fuel cell cannot fail to stimulate electrochemists who have at their disposal readily available supplies of free radicals generated at will at the electrodes to venture more daringly into the field of preparative organic chemistry.

ERIC K. RIDEAL

SYMPOSIUM ON PERSONNEL DOSIMETRY

Personnel Dosimetry Techniques for External Radiation Their Application in Nuclear Installations. (Proceedings of the Madrid Symposium, 1–5 April, 1963.) Pp. 510. (Paris: Organization for Economic Co-operation and Development, European Nuclear Energy Agency; London: H.M. Stationery Office, 1963.) 32 F.; 47*s.* 6*d.*; 8 dollars.

THIS record of the symposium on "Personnel Dosimetry Techniques for External Radiation" contains 28 papers, 20 in English and 8 in French with abstracts in both languages, presented at 7 scientific sessions. The symposium was introduced by Dr. A. S. McLean, of the U.K. Atomic Energy Authority, with an address entitled "Perspectives in Radiation Dosimetry".

The first scientific session, with Prof. R. M. Sievert (Sweden) as chairman, dealt with protection norms and photographic emulsions. H. Jammet (France) compared the biological aspects of radiation protection with health requirements for protection against occupational diseases. L. S. Taylor (United States) considered social and legal problems in applying norms and the inflexibility of numerical values in legally binding codes. Margarete Ehrlich (United States) spoke on physical considerations of film dosimetry including side effects, and evaluation procedures.

Film dosimetry was continued in the second session, under the chairmanship of Dr. A. S. McLean. F. Duhamel and G. Soudain (France) reviewed the present-day practice of the Commissariat à l'Energie Atomique. Radiation workers in Britain will be particularly interested in the description, by M. J. Heard and B. E. Jones (United Kingdom), of the new film holder with six filtered and one unfiltered areas developed by the Atomic Energy Authority and the Radiological Protection Service. The third paper, which is not listed in the table of contents, was by H. Dresel (Germany) and described the universal film holder for neutrons and mixed γ-, β-, and X-rays designed at the Radiologisches Institut der Universität, Freiburg i. Br. The session concluded with an interesting paper on biological methods in personnel dosimetry by Prof. E. H. Graul (Germany). Electronic instruments have been used for the counting and size measurement of formed blood elements before and after ultrasonic resistance tests and for rapid resistance measurements on erythrocytes and leucocytes. Results obtained after various radiation exposures were presented.

The third session, under the chairmanship of Dr. C. Polvani (Italy), dealt with physical methods of dosimetry and dosimetry of neutrons. W. Hanle and A. Scharmann (Germany) described solid-state dosimeters. Prof. R. M. Sievert emphasized the importance of dose-rate in addition to integrated dose and gave details of personal dose-rate meters. J. A. Dennis (United Kingdom), and A. H. W. Aten, jun., G. Samson, G. A. Brinkman, and J. W. Dalenberg (The Netherlands) presented papers on activation techniques for neutron dosimeters, considering in particular the use of phosphorus-31, sulphur-32, gold-197 and indium-115.

Neutron dosimetry was continued in Session 4, under the chairmanship of Prof. E. H. Graul, when three papers were read on recoil proton emulsions. G. Portal (France) discussed the problems of rapid analysis in mass employment of track films. Absolute spectrometry was described by P. Amadesi, A. Cavallini and O. Rimandi (Italy), and V. Mejdahl and Miss C. R. McCarthy (Denmark) reported on the use of induced fading to reduce the γ-ray blackening without seriously affecting the density of the proton tracks. Two papers followed on dosimetry of very high-energy radiations with F. P. Cowan (United States) reporting on the experience at the Brookhaven National Laboratory and J. Baarli and J. Dutrannois on that at CERN.

Session 5, with Dr. L. S. Taylor (United States) as chairman, was devoted to new developments. D. H. Peirson (United Kingdom) described the semi-automatic densitometer and track-counting equipment at Harwell. The densitometer gives an immediate print-out of the equivalent γ-ray dose, and provides a punched tape for subsequent automatic computation of the true dose. The track counter has been developed with glass-backed emulsions and detects track-lengths down to 5 μm, which is equivalent to a neutron energy of 0·5 MeV.

J. H. Schulman, F. H. Attix, E. J. West and R. J. Ginther (United States) dealt with thermo-luminescent dosimeters as attractive replacements for film badges. They are linear in response from 10^{-3} to 10^5 rads, dose-rate independent from 10 mr./min to at least 7,000 r./min, and, with appropriate filtration, independent of γ-ray energy from 40 keV to more than 1 MeV. M. Ladu, M. Pelliccioni, and E. Rotondi (Italy) then described a γ-insensitive fast neutron detector with good angular response and the ability to measure 1/10 m.p.l. G. Cowper (Canadian not American, p. 364) reviewed advances in dosimetry at Chalk River. The session concluded with remarks (not listed in the table of contents and with 'mrad' instead of 'Mrad' in the last equation, p. 367) by W. Minder (Switzerland) on chemical dosimeters which are not yet sufficiently sensitive for personnel dosimetry.

In Session 6, under the chairmanship of Prof. L. Bugnard (France), H. Joffre (France) and K. Becker (Germany) spoke on some of the problems, capabilities, and limitations of methods of personnel dosimetry. A number of spelling and other mistakes appear in the latter paper. N. Adams (United Kingdom) then presented an important paper (with an error in the ordinate scale of Fig. 1) directly relating absorbed dose in an organ to the apparent exposure dose given by the quick assessment of a film badge. A. Lafontaine (Belgium) made a plea for an interpretation of the biological and medical significance to accompany each statement of the physical dose.

The final session of the symposium, under the chairmanship of Dr. S. Halter (Belgium), heard four reviews of dosimetry practices of the national atomic energy organizations of the United States (D. M. Ross), Britain (W. A. Langmead), France (P. Candes, J. M. Lavie, and M. Bricka), and Spain (E. R. Rodriguez and R. G. del Campo).

The book is a useful collection of papers and its value is increased by the adequate reporting of the discussion which followed each presentation. D. Hughes

PROGRESS IN OCEANOGRAPHY

Progress in Oceanography
Vol. 1. Edited by Dr. M. Sears. Pp. vii+383. (Oxford, London, New York and Paris: Pergamon Press, 1963.) 100*s*.

PROGRESS in Oceanography is intended to be the first of an annual series of volumes with which it is hoped to keep oceanographers, and others interested in the sea, up to date with the rapidly expanding field of oceanography. The approach of the publishers is two-fold; to present reviews of the present status of currently important fundamental aspects of the subject, and to provide a medium for the publication of papers on original research of wide interest, particularly those which are longer than those generally published in scientific journals. In addition, it is hoped to publish preliminary accounts of work in which new methods or approaches are used. Chapters lying within each of these headings are included in the present volume.

In the first chapter, E. Seibold describes recent work carried out at the University of Kiel on the transport of near-shore sand. A well-documented review of the methods which have been used in the investigation of this problem is presented. An outline is also given of the procedures developed at Kiel for the study of sand transport; these include the examination of the structures and internal structures of the sediments and their petrology. The results obtained by the application of these new techniques to the Baltic and North Seas will be of interest to both geologists and those engaged in coastal engineering.

The longest chapter in the book (124 pages) is essentially the Ph.D. thesis presented by D. C. Blanchard at the Massachusetts Institute of Technology. It is devoted to a rather lengthy and highly speculative quantitative study of the electric charge separating at the surface of the sea, and seems out of place in a book of this type.

The total suspended organic matter in the upper layers of the sea (in terms of carbon) appears to average about one-tenth of the total dissolved organic carbon. Zooplankton and fish represent only a small proportion of it (c. 2 per cent and 0·2 per cent respectively). The major part of the suspended matter (80 per cent) consists of detritus mainly derived from dead phytoplankton, together with lesser amounts of fæcal pellets and organic material derived from the land. Phytoplankton constitutes the remaining 20 per cent, amounting to an annual production of organic carbon in the hydrosphere of c. 3×10^{10} tons. The importance of the role of the suspended matter in the sea in the marine food chain is only now being appreciated. Since much of the recent work on this subject has been carried out at the Nanaimo Biological Station of the Fisheries Research Bureau of Canada, the excellent review of this topic by T. R. Parsons is particularly timely. A very useful and thorough account is presented of the determination and chemical composition of both phytoplankton and detritus. In a further section the geographical distribution of these types of particulate matter and of bacteria, fungi and yeasts is described. The chapter ends with a summary of the literature on the utilization of all these organic materials as sources of food for secondary producers. Our knowledge of this important topic is at present very fragmentary but is rapidly expanding, and it is to be hoped that the publishers will persuade Dr. Parsons to review the subject again in a few years time.

In a chapter entitled "The Salinity Problem", Cox has given an authoritative and critical, but rather irritatingly chatty, account of methods for the determination of chlorinity and salinity which will be of interest to all oceanographers. The section on conductivity salinometers is of particular value as it embodies an account of the author's personal experience with many types of these instruments, and gives a useful assessment of their precision.

The final chapter of the book is by F. C. Fuglister; it describes a comprehensive investigation of the Gulf Stream system undertaken in 1960 by the Woods Hole Oceanographic Institution. The larger part of the chapter is taken up with diagrams of sections and with tables of oceanographic station data which seem rather out of place in a book of this type.

The book is attractively produced and stoutly bound and should be in the library of every oceanographic institution. However, its contents are so varied in subject that it is doubtful whether any individual would wish to spend £5 on it for the one or two chapters which may be of interest to him. The appearance of other volumes in this series will be awaited with interest. J. P. Riley

DEVELOPMENT OF MODERN DIURETICS

Diuretics
Chemistry and Pharmacology. By George deStevens. (Medicinal Chemistry: a Series of Monographs, Vol. 1.) Pp. xiii + 186. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 7 dollars.

OVER the past seven years important advances in medicinal chemistry have made available for clinical use a number of diuretics which are well tolerated and effective when given orally. In the previous thirty-five years, the mainstay of diuretic therapy had been the group of organic mercurial compounds of which mersalyl was probably the most popular in this country. Chance observation by Vogl, a third-year medical student in Vienna, had directed attention in 1919 to the diuretic potential of a mercurial drug which was being used for the treatment of syphilis. In spite of extended investigations, only a limited number of organic mercurials came into clinical use and among them none was entirely satisfactory when given other than by injection. While there were many miscellaneous medicinal substances which could provoke a diuresis and some were active by mouth, there was no drug available other than an injectable organic mercurial that could be relied on for a potent and sustained diuretic action without more or less serious undesirable effects.

The discovery of the inhibitory action of sulphanilamide on carbonic anhydrase and the rational explanation of its acidotic effect led to the clinical testing of its diuretic activity in 1949. Krebs had meanwhile published an account of the carbonic anhydrase inhibiting activity of a number of cyclic sulphonamide derivatives. Further extensive work in several laboratories resulted in the marketing of acetazolamide, which deStevens calls "the first clinically effective, non-mercurial, orally active diuretic drug". Until about 1958, this drug was used as a reasonably satisfactory substitute for organic mercurial compounds, when a moderate diuresis was required. Its use was subject to the limitations that its effectiveness waned as the metabolic acidosis developed and that excessive potassium loss might occur during its use.

Other sulphonamides were investigated by Sprague and Beyer and their colleagues. This work led to the *m*-benzene disulphonamides including dichlorophenamide and 5-chloro-2,4-disulphamylaniline, which had diuretic properties closer to those of the mercurials and differing from acetazolamide. Their action in man is characterized by a greater loss of chloride rather than bicarbonate ions and a significantly lower incidence of acidosis and refractoriness. Novello and Sprague then described the preparation of chlorothiazide by ring closure of 5-chloro-2,4-disulphamylaniline. At about the same time, hydrochlorothiazide was synthesized by deStevens and his colleagues. These were the forerunners of a series of thiazides of which several have found extensive clinical application.

The major part of this monograph is devoted to the sulphonamide and benzothiadiazine series of diuretics. The historical background of developments in these series of drugs makes interesting reading. The account of structure-activity relationships is of special value. Another important chapter is that dealing with substances which either antagonize the action of aldosterone or interfere with its synthesis. Other substances which have been used as diuretics are dealt with briefly, as befits their relative unimportance in therapeutics.

This is a valuable review which emphasizes particularly the chemical aspects of the subject. The treatment of the physiology of renal function is starkly simple and some errors have crept in. Thus, on p. 48, sodium carbonate is said to be formed by the union of bicarbonate ions with sodium ions in the tubular cells. There is also a very brief account of the pharmacological evaluation of diuretic action. Chapter 9 includes an assessment of the place of diuretics in the treatment of hypertension. The coverage of the biological activities of the diuretics is not comprehensive. The actions of thiazides—and of more recently introduced drugs such as triamterene—on urea, uric acid and glucose metabolism, are not mentioned. However, since the main emphasis of the monograph is on chemical aspects, especially structure-activity relationships, of diuretic drugs, these deficiencies are less serious. There is an adequate index and the book is well produced. The titles announced for further volumes in this series of monographs (some have already appeared) suggest that it will be a very valuable venture. D. R. WOOD

PSYCHOLOGIST'S BEDSIDE BOOK

Readings in Psychology

Edited by Prof. John Cohen. Pp. 414. (London: George Allen and Unwin, Ltd., 1964.) 52*s*. 6*d*. net.

THE collection, under one cover, of papers previously published elsewhere can be justified on the grounds either that it gives access to papers of historical merit, or that it brings together the contribution of experts in a particular field. But when the chapters are not classics and when the spread of specialities is broad, justification is harder to find. That is the situation with *Readings in Psychology*. Of its twenty-three chapters, only six appear to have been written especially for the book. The remainder are reprints of papers, chapters in textbooks, and presidential addresses to various learned societies.

The best indication of the book's coverage can be obtained from a list of its chapters: Cohen, a perspective for psychology; Oldfield, experiment in psychology—a centenary and an outlook; Burt, Francis Galton and his contributions to psychology; Meredith, models, meanings and men; Inhelder, some aspects of Piaget's genetic approach to cognition; Mace, homœostasis, needs and values; Zangwill, physiological and experimental psychology; Steinberg, aspects of psychopharmacology: drug-induced changes in emotion and personality; Vernon, attention and visual perception; Drever, perceptual organization and action; Humphrey, 'fifty years' experiment on thinking; Bowden, thought and machine processes; Mackay, information theory in the study of man; Summerfield and Legge, information theory and perception; Cohen, contact between minds; Hunter, the organization of memory; Vernon, the psychology of intelligence and *g*; Fraisse, the sources of emotion; Broadbent, response to stress in military and other situations; Hearnshaw, temporal integration and behaviour; Glover, research techniques in psychoanalysis and in general psychology: an essay in contrasts; Rodger, the effective use of man-power; Thorpe, some concepts of ethology.

Is there a hidden thread of continuity under this apparent hotch-potch? Prof. Cohen, in his foreword, points out that the sequence of chapters is methodical, but by this he appears to mean merely that the first couple of chapters are concerned with historical issues, the next few are theoretical, the next physiological and so on—a clump of chapters dealing with one set of topics is followed by another clump dealing with another set, but the ordering of these clumps is arbitrary and could be altered without affecting the merit of the book. Such a minimal degree of ordering gives no sense of continuity to the reader, who, if a non-psychologist, would be well advised to go elsewhere if he is seeking general information about the subject; from this volume he will only obtain an impression of an enormously wide, fragmented discipline, if discipline at all.

What then is the object of such a book? In view of the choice of authors—all except two are British—it would seem that one purpose is to publicize the contributions of modern British psychologists. As a corrective to the parochialism of much American writing, such a step is to be welcomed, but it is unfortunate that it had to take this form. How much better if these same contributors would combine forces to write a general textbook.

Readings in Psychology has to be dipped into, and, approached in this manner, it could be both instructive and enjoyable. Many of the chapters are clearly written—possibly a result of their earlier delivery as spoken papers. Some report recent research but one or two are quite out of date although written within the past ten years. It is equally irritating to be confronted with a chapter which has not been revised at all as with one which has a postscript pointing out its present-day inadequacies. The authors of these chapters should have been asked to contribute new articles or at least to remedy the deficiencies in the originals.

Perhaps the book can best serve psychologists as a bedside book. D. W. FORREST

DIAGNOSTIC FEATURES OF THE DIGENETIC TREMATODES

Keys to the Trematodes of Animals and Man.

By K. I. Skrjabin and others. Translated by Raymond W. Dooley. Translation edited by Hisao P. Arai. Pp. xvi+351. (Urbana, Ill.: University of Illinois Press, 1964.) 10 dollars.

FOR more than fifteen years (1947–62), Academician K. I. Skrjabin and his staff at the Helminthological Laboratory of the Academy of Sciences of the U.S.S.R. laboured to produce twenty volumes with a total of 14,000 pages entitled *Trematody Zhivotnykh i Cheloveka* (Trematodes of Animals and Man), an enormous compilation of taxonomic data on digenetic trematodes which still requires four volumes for completion. Skrjabin's initial idea of producing eight to ten volumes of information about genera became an ambition to define by means of keys and descriptions all the known species of Digenea and to include lists of hosts, data on distribution and some information about life histories.

Helminthologists unable to read Russian cannot utilize this fund of information and, because a complete translation could not be envisaged, the decision was made in certain quarters to do the next best thing and translate abstracted essentials for presentation in the compendium under review here. The book is divided into nearly equal halves, one containing keys to taxonomic groups and lists of references and the other more than nine hundred line diagrams and a subject index. The selection and translation of essential data made a formidable task for Hisao P. Arai and Raymond W. Dooley of the University of Illinois, who used Whitfield's (1958) transliterated form of the Cyrillic alphabet and worked to a rigorous discipline. We have to remember that many descriptions of species are excluded and that only those citations to the original literature which are rendered in Cyrillic in the major work are presented, which means that readers refer to the twenty volumes for particulars about numerous non-Russian references.

The constituent compilations of the original volumes were published as they became available, so that they are not in any conventional order, and this disorder has been emphasized by abridgment. Moreover, the taxonomic scheme is incomplete, so that the reader cannot examine the classification of the Digenea as a whole and, indeed, is irritated and frustrated in his efforts to do so. On p. 3 the major groups are indicated. The Digenea is divided into the sub-subclasses Gasterostomatoinei and Prosostomatoinei and the former group is not mentioned again, relevant subsequent references being to the subfamilies of Bucephalidae and literature concerning an order named as Bucephalida (pp. 178–179). Similarly, the Prosostomatoinei is divided into the superorders Aspidogasteriformes and Fascioliformes, but the former receives no further mention, although the suborder Aspidogastrata is divided into its two families on p. 50. The Fascioliformes is divided into ten orders (the Alcicornata, Didymozoata, Fasciolata, Faustulata, Heronimata, Notocotylata, Paramphistomatata, Sanguinicolata, Schistosomatata and Strigeata), but only two of these (Notocotylata and Paramphistomatata) are completely resolved into families. On p. 44 the Schistosomatata is named as a suborder and divided into two superfamilies Sanguinicoloidea (already designated as an order) and Schistosomatoidea, which receives no further mention, the following key referring to subfamilies of the family Schistosomatidae (p. 47). The reader will be disappointed often in this way and may conclude that the entire taxonomic scheme was established with pre-ordained classes, subclasses, sub-subclasses, superorders, orders, suborders, superfamilies, families and lower groups some of which remained unresolved.

In conjunction with the primary disarray, this lack of finality gives the impression of bewildering muddle where clarity might have prevailed. Some dissatisfaction may be felt also about the use of keys which were soon outmoded because of subsequent revision or outdated by the appearance of new species. One great drawback of keys is that they become unusable when new species appear and must be completely redrafted. The Russian keys are often very detailed but, like others, are not infallible. They have been duplicated for both subfamilies and genera of Echinostomatidae (pp. 8–10 and 101–102) and then remade (pp. 102–103) with new inclusions, as also for Dinuridae (pp. 81 and 150), Lecithasteridae (pp. 82 and 118) and Lecithochiridae (pp. 87 and 140). The reader is somewhat bewildered by the apparently belated promotions and, sometimes, unexplained omissions.

When examined carefully, the book indicates clearly the somewhat alarming impression of a rapidly expanding classification of the Digenea, alarming because promotion to family rank is sometimes from the status of genus, where taxonomic characters used often fail to receive universal acceptance. We realise how difficult trematodes are to classify only when we take into consideration certain facts: they exist, when alive, in a semi-liquid state with a minimum of skeletal structure, are very extensile and contractile, continue to grow and sometimes alter their bodily proportions long after attaining sexual maturity and, indeed, throughout life, show variability according to various phases of sexual life, appear sporadically and often in small numbers and, above all, are liable to show morphological artefacts on account of preservation and mounting for microscopical inspection. In reviewing the recent taxonomic scheme of Yamaguti[1], my analysis showed that out of 102 families, fifty-nine contained no more than four genera and thirty-one only a single genus. Skrjabin recognizes 125 families, but the discrepancy between the two schemes is much greater than these figures indicate. Forty-two families named by Skrjabin are not recognized by Yamaguti, although one (Elytrophallidae) is mentioned in a footnote and another (Megasolenidae) is regarded as a synonym. Two other families (Aerobiotrematidae and Stichocotylidae) are not even represented by genera in Yamaguti's scheme, and seven others (Faustulidae, Lecithochiriidae, Liocercidae, Microscaphiidae, Opisthoporidae, Ratziidae and Xenoperidae) are represented only by genera. The remaining thirty-one families are represented by Yamaguti as subfamilies: seven are promotions from the Allocreadiidae, six from the Paramphistomatidae, three from the Hemiuridae, two from the Opisthorchiidae, two from the Troglotrematidae and eleven respectively from the families Acanthocolpidae, Brachycoeliidae, Callodistomatidae, Cyathocotylidae, Diplostomatidae, Heterophyidae, Microphallidae, Plagiorchiidae, Pronocephalidae, Protorodiplostomatidae and Strigeidae.

On the other hand, twenty-one families (six of them new) which are named by Yamaguti do not appear in Skrjabin's scheme. Three of them (Allocreadiidae, Bhaleraoidae and Mesometridae) are unrepresented by genera, nine of them (Anenterotrematidae, Aporocotylidae, Botulidae, Brahamputrotrematidae, Eumegacetidae, Ommatobrephidae, Pachypsolidae, Paragonimidae and Rhopaliasidae) are represented only by genera, and nine of them (Apocreadiidae, Brachycoeliidae, Hasstilesiidae, Leucochloridiidae, Moreauiidae, Nasitrematidae, Pleorchiidae, Telorchiidae and Waretrematidae) are represented by subfamilies. Readers may rightly infer that in the four Russian volumes still to appear some of these families and possibly others will be named.

Another source of bewilderment for the reader is provided by the lists of literature which are introduced frequently into the text. Innumerable references which have value in the series of original volumes are useless in this book because they have no bearing on the diagnosis of digenetic trematodes. Altogether, these references take up about one-fifth of the text. On pp. 17–20, the first five of a long list of papers on fascioliasis concern liver fluke in an eleven-year-old girl, distomatiases of children in Turkestan, methods of 'de-helminthization' of manure, the treatment of sheep with carbon tetrachloride and methods of introducing medicinal substances into small animals. Even more incongruous are references to allergic skin reactions (p. 50), heredity and variability (p. 58), anoplocephalid tapeworms (p. 59), migrations of fishes (p. 77) and nematodes of poultry (p. 157), as well as many items cited "no title given". Space has been far better spent on figures, which are miniatures of those in the Russian volumes and might have been augmented, but indications of size are not consistently given in either illustrations or text and would have been of great advantage to the diagnostician. The book will not be popular but will have many dour users, who will peruse it just as grimly as I did, until I noticed the misprinted reference to "the helminth fauna of sand-papers".

BEN DAWES

International Review of Connective Tissue Research

Vol. 1. Edited by David A. Hall. Pp. xiii+401. (New York and London: Academic Press, 1963.) 14.00 dollars.

THE first volume of *International Review of Connective Tissue Research*, a new periodical, contains eight review articles. It is not idly called 'international' since the authors come from seven different countries—Scotland, Holland, Denmark, Hungary, India, Australia and England.

The past decade has seen a great increase in real knowledge of connective tissues and their components, and any method of assembling this is potentially valuable. There are now a number of examples of this type of reviewing periodical, which would be most valuable if it could give a reasonably complete running account of the subject. However, in practice they usually contain a heterogeneous collection of articles of variable interest and value. For every one you want you must buy and carry perhaps two or three others, and often more. This seems to be inevitable, and judgment must therefore be based on the best articles. In this volume there are certainly two which should be of wide interest and value, on the structure of collagen by G. N. Ramachandran and its metabolism by D. A. Lowther. The articles are complementary and have tables in common. There is a useful article on calcification of skeletal tissues by S. M. Weidmann. I also found J. Balo's article on atherosclerosis fresh and interesting.

In short, there is useful material in this volume, mainly for the specialist who is already familiar with some aspect of the subject. It would be more generally useful if the bibliographies gave titles, even if some of the articles had to be shortened and 17 pages of author index left out. There is a subject index, but it is only 5 pages long.

The Mushroom Hunter's Field Guide

By Prof. Alexander H. Smith. Revised and enlarged edition. Pp. 264 (188 figures). (Ann Arbor: University of Michigan Press; London: The Cresset Press, Ltd., 1963.) 45*s*. net.

LIKE its predecessor, *The Mushroom Hunter's Field Guide* is written for the amateur in non-technical style and has been considerably enlarged to include accounts of 188 species as against 124 in the original book. However, since Prof. A. H. Smith has altered the selection of species described in the first edition by deleting some and adding others, it follows that the book, as revised, covers an appreciably different range of fungi. The text has been modified, although the format remains much the same, with data grouped under the headings "Identification marks", "Edibility" and "When and where to find it". Furthermore, while each species is illustrated with black-and-white photographs of an extremely high standard, many of those previously used have been replaced. Another innovation is that 89 species are also illustrated in colour. Here one should note that the numbers of the captions refer to the species number in the text and are not in a running sequence.

In general the descriptions of the species, although of necessity brief, are adequate. However, just occasionally brevity has resulted in omission of important information. Thus I would have expected some reference to the fact that *Agaricus placomyces* becomes bright yellow on bruising, especially as this reaction clearly separates it from *A. silvaticus*—a species with which it is liable to be confused according to Prof. Smith (p. 197).

As to the addition of coloured plates, these will undoubtedly help to increase the appeal of this book. In the preface Prof. Smith writes: "Illustrations in color, however, are the most difficult aspect of a publication on mushrooms. To be of help rather than to be misleading, the color work must be accurate". I share these sentiments, but I'm not sure that Prof. Smith has altogether succeeded in his aim; although a number of the coloured photographs are very good, others are bad. Thus on Plate 124*a* *Amanita muscaria* is shown as blue, whereas it must be assumed that the plate represents the white form of the species. Likewise *Lactarius rufus* is depicted as bright pink, whereas this fungus should be rich reddish-brown. Similarly the illustrations of *Lycoperdon pyriforme* and *Armillaria mellea* are so poor as to be scarcely recognizable. Nevertheless, taken as a whole, the coloured plates are superior to many which have been used to illustrate mycological works in recent years.

Apart from these relatively minor criticisms, I have no hesitation in recommending this excellent book to those living in North America who wish to obtain a knowledge of the larger fleshy fungi, be it for general interest or from the point of view of gastronomy. Furthermore, those who have used *The Mushroom Hunter's Field Guide* will want to purchase the revised edition since it covers an appreciably increased range of species. For those with an interest in mycology outside North America, this work will naturally have a more restricted appeal, but since it is attractively produced, reasonably priced, and of very good value, they too may wish to add it to their bookshelves.

D. A. Reid

Les Maladies des Plantes Maraichères

Vol. 1. By C. M. Messiaen et R. Lafon. Pp. 153. (Paris: Institut National de la Recherche Agronomique, 1963.) 21 F.

THIS practical little manual of vegetable crop diseases is largely based on the experience of the authors in southern France. After brief but adequate introductory chapters, describing the agents of disease in plants and the principles of plant disease control, come chapters devoted to diseases of the following crops: tomato; egg-plant and capsicum; cucurbits; haricot beans; peas and broad beans; celery; and parsley. Symptoms are illustrated by simple but effective line drawings, supplemented by a few photographs.

R. W. G. Dennis

Underwater Acoustics

Proceedings of an Institute sponsored by the Scientific Affairs Committee of the North Atlantic Treaty Organization and conducted by the Pennsylvania State University at the Imperial College of Science and Technology of the University of London, July 31–August 11, 1961. Edited by V. M. Albers. Pp. xiii + 354. (New York: Plenum Press, 1963.) 12.50 dollars.

UNFORTUNATELY the main title of this book, and the one it is likely to be known by, is a little misleading. It does not pretend to be a text-book on underwater acoustics but is a compilation of the papers presented at a symposium, sponsored by the North Atlantic Treaty Organization, in London in 1961. Nevertheless, the standard of the papers given is high and the book may be used for specialized reference in certain fields of underwater acoustics.

Papers include work on piezoelectric transducers, explosive sources, directivity and scanning, internal waves, scattering, ambient noise, flow noise and model propagation studies. Certain important areas of the field are not covered, notably: controlled propagation experiments in the sea and their theoretical interpretation, non-piezoelectric transducers, and the design of transducer arrays including reference to the interaction problem between elements.

It is clear that this is a difficult subject to present adequately since the scientific and engineering matter covered by the title *Underwater Acoustics* is very large; and the problem is complicated by the various grades of security imposed by national and international organizations. The organizers of this symposium are to be congratulated on pioneering such a meeting in the United Kingdom.

OBSERVATION OF THOMSON AND CO-OPERATIVE SCATTERING OF RUBY LASER LIGHT BY A PLASMA

By A. W. DeSILVA*, D. E. EVANS and M. J. FORREST

Culham Laboratory, U.K. Atomic Energy Authority, Abingdon, Berks

WHEN monochromatic light is directed on to a plasma, a fraction of the light undergoes scattering on the free electrons, the motion of which introduces Doppler broadening. A number of theoretical papers, for example, Dougherty and Farley[1], Fejer[2] and Salpeter[3], have dealt with the problem of the resulting wave-length spectrum and have shown that it can be characterized by a single parameter:

$$\alpha = \frac{\lambda}{4\pi D \sin \theta/2}$$

where λ is the wave-length of the incident light, D the plasma Debye length and θ the angle to the incident beam at which the light is scattered. Theory shows that for $\alpha < < 1$ the spectrum takes the form of a gaussian the width of which is given by the average velocity of electrons at a temperature T_e, decreased by a geometrical factor, sin $\theta/2$. This has been called incoherent or Thomson scattering. For $\alpha > 1$ the electrons behave collectively and their motion is determined in part by the motion of the ions. The spectrum is expected to consist of a central feature the width of which depends on the sound velocity in the plasma, together with two peaks shifted on either side of the centre by an amount given by the electron plasma wave velocity.

We have designed an experiment in which the correct choice of plasma parameters allows us to detect both the ($\alpha < < 1$) mode and the collective ($\alpha > 1$) mode in the same plasma merely by altering the directions from which scattered light is observed. The upper part of Fig. 1 illustrates the experimental arrangement for observation of the $\alpha < < 1$ feature. A Q-switched ruby laser produces a 2·5-MW pulse of light at 6935·5 Å having a spectral width of 0·05 Å (ref. 4) which is introduced into the plasma through a suitably baffled entry tube and is carried away through an exit tube which terminates in an efficient light trap.

The plasma is a pulsed hydrogen arc formed in 200 m torr of hydrogen between a pair of stainless steel electrodes 50 cm apart. An axial magnetic field of 5 k.gauss maintains the plasma for about 350 μsecs during which a peak current of about 20 k.amp flows. Stark broadening measurements of the $H\beta$ line have given an electron density of 9×10^{14} cm^{-3} and subsequent measurements of the width of the $\alpha < < 1$ feature gave an electron temperature $kT_e = 2{\cdot}2$ eV. This means $\alpha < 1$ for $\theta > 16°$. Observations were made at 170° ± 1·5° and 10° ± 1·5° for which $\alpha = 0{\cdot}15$ and $\alpha = 1{\cdot}7$ respectively. In both cases the detection optics were based on a conical lens, placed concentric about the laser beam, which accepted all the light

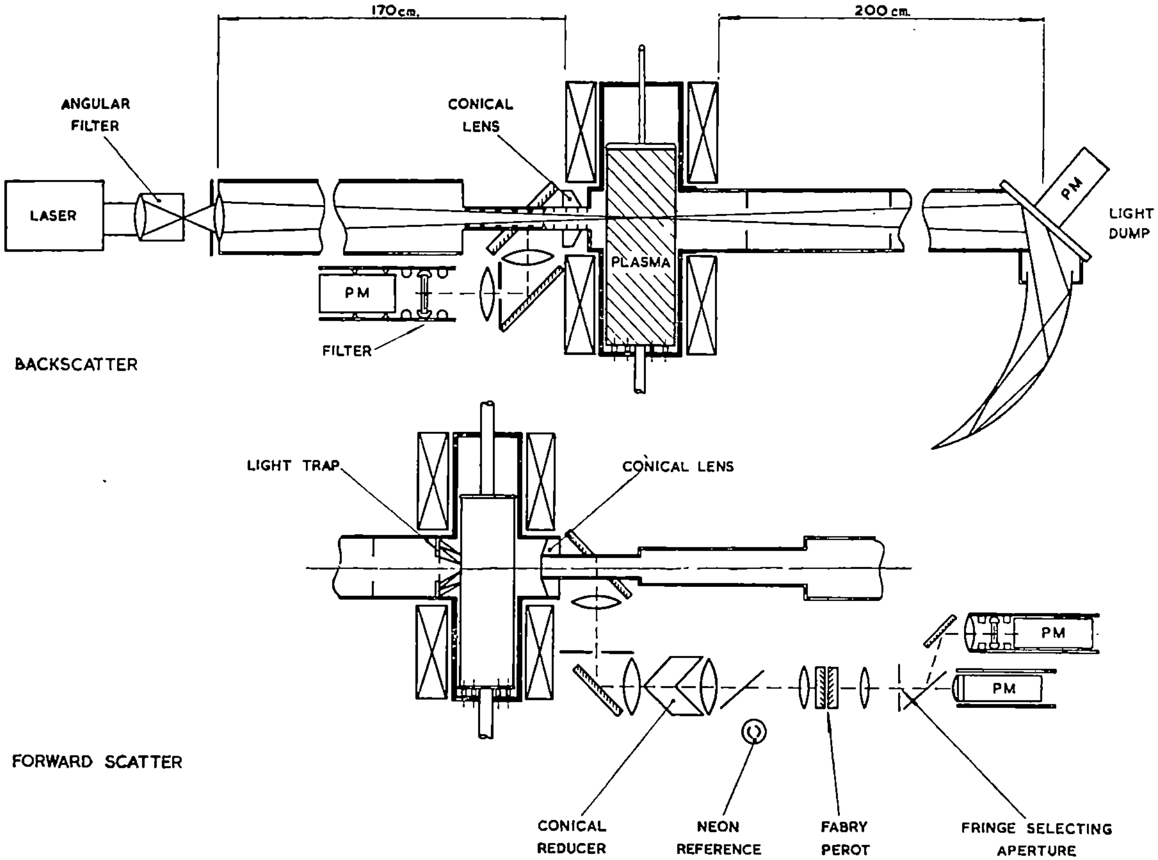

Fig. 1. Schematic diagram of experimental arrangement

scattered at the preselected angle from the plasma. In the back-scatter experiment, spectral resolution was obtained by tilting a nominally 3 Å band pass interference filter centred at 6943 Å. An E.M.I. 9558*A* photomultiplier with an S_{20} (trialkali cathode) response detected the light transmitted by the filter. The lower part of Fig. 1 shows the experimental arrangements adopted for forward scattering measurements. The optical train and detector are essentially the same as before, but since the acoustic feature was expected to have a width of about 0·2 Å, the tilting filter was abandoned in favour of a scanning Fabry-Perot interferometer.

Fig. 2 shows the results of the scattering experiment at 170°, and displays the total scattered signal as a function of wave-length. It therefore includes stray scattering of the main beam from the walls of the vessel, etc., and this appears as an anomalous peak at the centre of the distribution. Measurements made in the absence of plasma (black circles) indicate that the stray light has been reduced to a manageably low level. The stray light spectrum, which is simply the instrumental shape of the filter and the detection optics, has been subtracted from the total signal and a Gaussian curve (half half-width 35 Å) has been fitted, from which it appears that the electron temperature $kT_e = 2{\cdot}2$ eV.

Fig. 3 displays the signal observed in the forward scatter position as a function of wave-length. In this case no correction for stray light was required since an observation made without plasma in the vessel showed that stray light and Rayleigh scattering on neutral hydrogen were undetectable. The spectral resolution of the system is restricted by the absolute light intensity available which has set a practical limit of 2 Å on the setting of the interferometer. The experimental points are consistent with an instrumental profile 2 Å wide, and one can regard this as an upper limit to the width of the feature being observed.

Nitrogen at a pressure of 0·25 atmosphere was substituted for plasma in the chamber and the intensity of light at the detector due to Rayleigh scattering was measured. The ratio of intensities of Rayleigh scattered light and light scattered by the plasma was $S_r/S_t = 8{\cdot}8$. The expected value of this ratio was calculated assuming the plasma-scattered light to be associated with a cross-section equal to about 0·5 the Thomson cross-section, as predicted by the theory of co-operative scattering. Rayleigh cross-sections were taken from George *et al.*[5]. The theoretical Rayleigh cross-section led to $S_r/S_t = 9{\cdot}0$ and the experimentally determined cross-section gave $S_r/S_t = 21$. We conclude that the intensity of the signal observed in the forward scatter experiment is consistent with scattering by the acoustic wave.

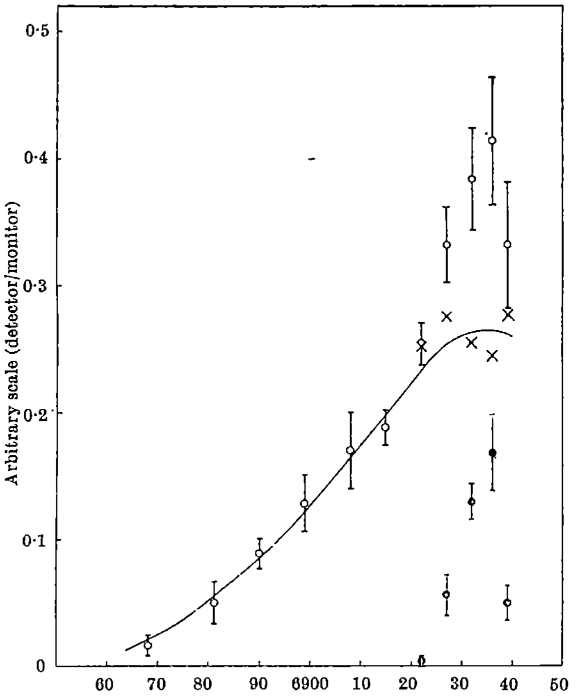

Fig. 2. Spectrum of light scattered at 170°. Laser wave-length 6935·5 Å. O, Scattered + stray light; ●, stray light alone; ×, scattered light alone

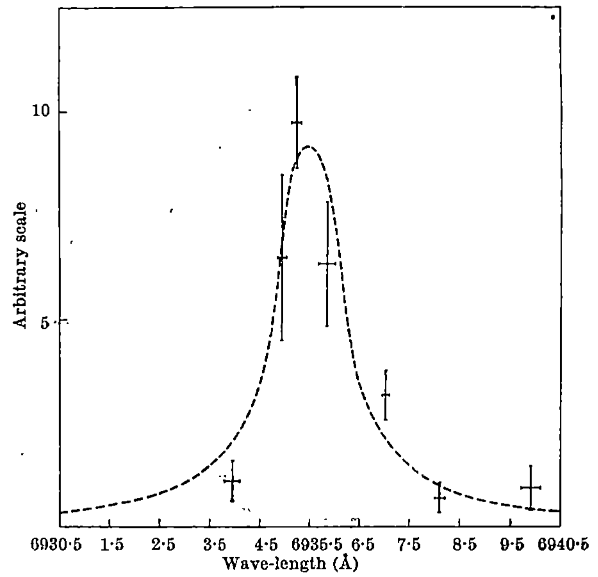

Fig. 3. Spectrum of light scattered at 10°. Laser centred at 6935·5 Å. Ion resonance $a = 1{\cdot}7$; - - -, instrumental line shape; stray light negligible

The width (< 2 Å) is also consistent with acoustic wave scattering, and at the same time rules out the possibility that the light scattered at 10° is due simply to Thomson scattering, for if this were so a width of $\dfrac{\sin 10°/2}{\sin 170°/2} \times 70$ Å $= 6$ Å would be expected.

It remains possible that there is a contribution to the observed forward intensity due to some effect apart from co-operative scattering. Photo-ionization of neutral hydrogen followed by immediate radiative recombination could produce spurious photons, but there are unlikely to be many, owing to the very short relaxation time (10^{-10} sec) compared with both the laser pulse length (2×10^{-8} sec) and the recombination time (10^{-3} sec). The intense electromagnetic field of the laser light in the plasma will produce photons at the laser frequency through stimulated emission of radiation. These will, however, be in phase with the stimulating field, and so will travel in the same direction as the principal laser beam. Again, only a negligible number are expected to reach the detector.

Work is proceeding to improve the strength of the forward scattered signal with the aims of measuring the width of the central peak and of detecting the satellites at the plasma frequency.

We thank Dr. R. Wilson and Dr. D. J. Bradley for their help and advice. One of us (A. W. DeS.) gratefully acknowledges the support of the National Science Foundation during a major part of the work.

EVOLUTION AND PREVENTION OF DRUG-RESISTANCE

By Prof. M. G. SEVAG and BARBARA ASHTON

Department of Microbiology, School of Medicine, University of Pennsylvania, Philadelphia

THE capacity exhibited by all organisms to develop tolerance for new environmental conditions has been an important factor in the continuing existence of life on Earth. It has also had adverse effects on some creatures. To man, one of the most disturbing of these effects is being manifested through the resistance certain microbes develop for the 'wonder' drugs he uses to counteract microbial diseases.

The peculiar capacity of pathogenic micro-organisms to develop strains which are resistant to drugs which on initial application are lethal to most individuals—and eventually to thrive on those drugs—did not come into clear focus until Paul Ehrlich *et al.* made their famous chemotherapeutic researches during the first decade of this century. Over the years, concern for these effects intensified as a greater variety of drugs was produced and wider use was made of them. With the advance of modern chemotherapy, microbial resistance to sulphonamides and antibiotics became a frustrating medical and scientific problem. More recently we have learned that similar adaptability occurs among the cells causing cancerous growth during treatment by radiation and chemicals, and that viruses may also develop this same kind of tolerance and thereby interfere with the therapy of viral infections.

Because of the danger of these effects, a large research effort is being made to understand and control them. Experiments are proceeding with a wide variety of antibiotics, individually and in combination; investigations are in progress on the mode of action of antibiotics; and comparisons are being made of the biochemical and genetic differences between normal and resistant strains. These investigations have not yet produced sure-fire measures for preventing the emergence of microbes or other micro-organisms that are resistant to antibiotics. The synergistic combination of antibiotics or drugs, by trial and error, is beset with uncertainties or may result in an antagonistic action. These trials have not produced a guiding principle to cope with the phenomenon of drug-resistance.

Prevention of the Emergence of Drug-resistant Strains*

In previous communications[1,2] it was reported that spermine in a combination with an antibiotic prevented the emergence of drug-resistant strains from *Staph. aureus*, *Escherichia coli* and *Aerobacter aerogenes*. In the work recorded here the antimalarial drug atabrine ('Quinacrine') is used as a substitute for spermine. In using atabrine we were guided by the fact that, like spermine and streptomycin, it complexes stably with nucleic acids and DNA is known[3] to be the carrier of the code for the resistance character.

We therefore entertained the idea that atabrine complexing with DNA could prevent the resistance-inducing action of an antibiotic on normal bacteria. This working hypothesis is supplemented by the following results.

The results with atabrine and various antibiotics are presented in Table 1. It is to be seen that chloromycetin, tetracycline, erythromycin, novobiocin, penicillin, sulphathiazole and streptomycin, each together with atabrine, exercise bactericidal action; in the absence of atabrine a staphylococcal strain of greater resistance emerges. Likewise, as shown in Tables 2 and 4, no resistant strain of *E. coli* emerges in the combined presence of streptomycin or sulphathiazole and atabrine. In Table 3, the results show that *E. coli* resistant to streptomycin are not prevented from growing in a combination of streptomycin and 250 μg of atabrine. On the other hand, the same resistant strain is killed by a combination of as little as 1 μg of sulphathiazole and 100 μg of atabrine; the contents of the system plated out on nutrient agar showed no colony growth.

Of special consideration is the effect of *p*-aminobenzoic acid (PABA) on sulphathiazole inhibition with and without atabrine (Table 1, systems 27–29). In the absence of atabrine sulphathiazole inhibition is either absent or readily antagonized by PABA. In the slower rate of antagonism by PABA of the sulphathiazole inhibition in the presence of atabrine, the specific preventive effect on bacteria of the latter two substances is eventually nullified.

A bacterial strain which had been sub-cultured once in streptomycin grew readily in the combination of this antibiotic and spermine or atabrine. In other words, once the resistance character is acquired by a strain a combination of atabrine or spermine and the antibiotic is ineffective. Indeed, two cells from a population which had grown for the first time in 100 μg streptomycin/ml., added to 100 million sensitive normal cells, grew freely in the presence of both streptomycin and spermine or atabrine. The results show that our system selectively eliminates all the 100 million sensitive cells and permits the multiplication of as few as two actually resistant exogenous cells. Had there been, therefore, as few as only two naturally occurring resistant cells in the inoculum of 100 million normal cells, our system would have selectively permitted their multiplication in a combination of the antibiotic and spermine or atabrine. On the other hand, we must take note of the fact that a resistant strain emerges from 100 million normal bacteria used alone as inoculum in a growth medium containing only the antibiotic. One may conclude, therefore, that these normal bacteria must have contained certain mutants which, possessing the potentiality of becoming resistant, were catalysed by the antibiotic to take on the resistant character. This mediation by an antibiotic is prevented from becoming an actuality in a combination of atabrine or spermine and the antibiotic.

Determination and Prevention of the Emergence of Cross-resistant Strains

As already discussed here, atabrine or spermine is ineffective in combinations with an antibiotic to which a bacterial strain has become resistant by one or more previous sub-cultures. However, atabrine or spermine is highly effective in combination with another antibiotic to which the bacterial strain has not been exposed before. In the absence of spermine or atabrine, a strain resistant to an antibiotic can become resistant also to a second or third antibiotic. Customarily, the ability of the penicillin-resistant strain to grow in streptomycin would be attributed to an unspecific cross-resistance against the latter antibiotic. On the basis of the current 'selection theory' of antibiotic resistant strains, the above facts may be interpreted to indicate that, either the penicillin-resistant

---

* The experimental procedures used throughout this investigation were the same as those used in the previous investigations[1,2].

Growth medium: Salts-glucose + 1 per cent casein hydrolysate + tryptophan 20 μg + 1 μg thiamine + 1 μg nicotinamide/ml.
Inoculum: 1×10^8 cells/5 ml. medium collected from a growth in 0·5 per cent glucose broth (Sevag and Barbara Ashton).

cells used as inoculum were double mutants, or they contained a certain number of double mutants, which were selected by streptomycin, yielding a population of cocci resistant to both antibiotics. However, because of the fact that the streptomycin-resistant cells are not susceptible to the combined action of streptomycin and spermine or atabrine, and because of the fact also that the penicillin-resistant cells were killed by the combination of streptomycin and spermine or atabrine, it would be reasonable to conclude that the penicillin-resistant strain was neither a doubly resistant mutant, nor possessed an unspecific cross-resistance to streptomycin prior to exposure to it. On the basis of the above facts, one may therefore be permitted to assume that the gradual emergence of a streptomycin-resistant strain from a penicillin-resistant strain results from an acquisition of a new resistance character. This acquisition also is prevented in the presence of spermine or atabrine[1].

Table 2. Prevention of the Emergence of a Drug-resistant Strain from the Normal Strain of *Escherichia coli* Strain *B* in the Combined Presence of Streptomycin and Atabrine

Inoculum: $1·0 \times 10^8$ cells/5 ml. of 0·5 per cent glucose-nutrient broth (Sevag and Barbara Ashton).

In hospital laboratories, this system offers a dependable and practical method to determine whether or not a strain carries cross-resistance to other antibiotics. By the use of this system one can also determine which antibiotic together with spermine or atabrine is the most effective to prevent the emergence of a strain with additional resistance characters from an already resistant strain.

Prevention of the Emergence of Resistant Strains in Systems Excluding 'Selection'

A direct experimental illustration of the specific effects of a drug and atabrine on the sensitive strain of *Staphylococcus aureus* is provided by the results presented in Fig. 1. In these experiments the possibility of selecting mutants as resistant strains assumed to occur naturally by the 'selection theory' is excluded. The growth rate was determined by colony counts. As inoculum 20–25 cells/5 ml. medium were used. Colony counts of the growth in the liquid medium were made at 0, 18, 24, 42 and 72 h. In the system with 100 μg sulphathiazole or 100 μg of atabrine, at no period was there a decrease in the number of cells. In sulphathiazole together with atabrine, the cell number remained constant during the first 24 h, then decreased gradually, and no colony grew at the 72-h period.

The fact that in sulphathiazole alone, or atabrine alone, the cell numbers remained constant for several hours before they began to multiply shows clearly that none was killed and there were no selections of the assumed 'naturally occurring mutants' from the initial inoculum of 4–5 cells/ml. Such a possibility is excluded also by the fact that all the cells were killed in the combined presence of sulphathiazole and atabrine, as would be expected if all were normal sensitive cells. The fact, however, that the normal cells grew in sulphathiazole after a short delay indicates that the drug exercised an action on the metabolism of the cells whereby the bacteriostatic action of sulphathiazole was nullified. The conclusions from these investigations are corroborated by the results of our previous work with Drs. Ishii[10] and Yokota[11], showing that in sub-lethal concentrations of sulphathiazole in which the cells survive from 50 to 82 per cent (determined by colony count), the mass of cells experience an increment of the folic acid synthesizing enzymes; thereby the inhibitory action of the drug is counteracted.

Berkeley Square House, London, W.1

THE RED BLOOD CELL

edited by C. W. Bishop and D. M. Surgenor

- covers the red cell from the viewpoint of basic cell biology.
- includes: red cell shape and structure, electrolyte equilibria and active transport, metabolic pathways, red cell interactions with antibodies, isoagglutinins, oxygen and carbon dioxide transport, and cryobiology.

(B356) Oct., 1964, 566 pp., 121s. 6d.

THE EPIDERMIS

edited by William Montagna and Walter C. Lobitz, Jr.

- details the developmental sequences and enzymic properties of the epidermis, protein synthesis, and the nature of the proteins.
- covers the ultrastructure of the epidermis in normal and pathological states.
- emphasizes functional ultrastructure.

(M816) Oct., 1964, 649 pp., 107s. 6d.

SELENIUM

GEOBOTANY, BIOCHEMISTRY, TOXICITY AND NUTRITION

by Irene Rosenfeld and Orville A. Beath

- investigates seleniferous geological formations, soils and plants as they relate to livestock poisoning and public health.
- evaluates the role of selenium in nutrition, particularly as to vitamin E deficiency diseases in animals.
- offers material of great value to specialists or graduate students in geology, soil science, botany, biology, veterinary science, industrial and human medicine, nutrition, and research workers in biochemistry.

THE HORMONES

PHYSIOLOGY, CHEMISTRY AND APPLICATIONS

edited by G. Pincus, K. V. Thimann and E. B. Astwood

REVIEWS:

Volumes 1 and 2—"*These . . . volumes are of classic proportions. They contain twenty-five chapters of rich material, ranging from botany through marine zoology to clinical medicine. In the best sections a most important goal is achieved; basic evidence is presented. Too many volumes in the past have been no more than annotated bibliographies. These are balanced, discursive and well written.*"
—THE NEW YORK TIMES.

Volume 2—"*. . . will prove most valuable to the serious student of endocrinology and those interested in experimentation in the field. The intent of the editors is a complete presentation of the subject at the research level. They have succeeded remarkably well in attaining this goal.*"—JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

(P328) Vol. 5, Oct., 1964, about 875 pp., 200s.

Detailed information available upon request

INTERNATIONAL SYMPOSIUM ON PHYSICAL PROCESSES IN RADIATION BIOLOGY

edited by L. Augenstein, R. Mason and B. Rosenberg

- discusses the core problem of radiation biology: How high energy packets (protons or particles) are absorbed, distributed and utilized in biological systems.
- emphasizes the nature of exciton processes, the mechanisms of charge transport in biological materials, the interactions of fast and slow electrons with model systems, the importance of liquid structures in determining the development of radiation damage, and the nature of the metastable species formed.

(A997) Oct., 1964, 377 pp.

METHODS OF ANIMAL EXPERIMENTATION

edited by W. I. Gay

- provides information on the most common methods for using animals as tools in the search for new biological knowledge.
- describes techniques to facilitate the most efficient use of research animals, and provides guidelines for their comfort and welfare.
- gives fundamental and well-developed techniques which will be useful to graduate students and experienced scientists who must consider variations in research approaches.

(G310) Vol. I, Nov., 1964, about 375 pp., 96s. 6d.

EXPERIMENTAL ENDOCRINOLOGY

A SOURCEBOOK OF BASIC TECHNIQUES

by M. X. Zarrow, J. M. Yochim and J. L. McCarthy

- includes material designed to give the student an appreciation of the whole animal.
- provides a text on the physiology and biochemistry of vertebrate and invertebrate endocrine systems.
- covers the source, nature, physiology, assay and mechanism of action of a hormone or related group of hormones, along with a section of experiments, procedures and techniques related to the gland under discussion.

(Z020) Sept., 1964, 516 pp., 107s. 6d.

THE MICROSCOPICAL CHARACTERS OF ARTIFICIAL INORGANIC SOLID SUBSTANCES

OPTICAL PROPERTIES OF ARTIFICIAL MINERALS

Third Edition

by A. N. Winchell and Horace Winchell

- provides the chemist or crystallographer with a means to identify optically characterized substances.
- offers a convenient, versatile, graphic summary of optical properties keyed directly to the full descriptions of the substances.
- facilitates the joint use of powder-diffraction data and optical properties by references to X-ray Powder Data, as well as to speed the confirmation of an identification.

Inoculum: about 1×10^6 cells/5 ml. of salts-glucose + 1 per cent casein hydrolysate medium (Sevag and Barbara Ashton).
* SM = streptomycin; ST = sulphathiazole.

Another more recent unexpected observation, to be reported elsewhere, is the profound change staphylococci experience by one or two sub-cultures in sulphathiazole alone. This experience renders staphylococci mortally sensitive to atabrine *per se*. As shown in Fig. 1, normal cells without such an experience survive atabrine with no difficulty.

Discussion

It has been variously reported that DNA is the genetic seat of the drug-resistant character of bacteria[3]. We thought, therefore, that an agent capable of complexing stably with DNA should in some manner influence the development of resistance behaviour of bacteria. Streptomycin[4], spermine[5], and atabrine ('Quinacrine')[6], and diamino acridines, such as acridine orange[7], complex with nucleic acids. DNA possesses acidic phosphate groups; spermine contains two secondary and two primary amino groups; atabrine contains, in addition to the acridine nucleus, one secondary and one tertiary basic amino groups in the aliphatic side-chain of the molecule, and streptomycin contains two guanido and one tertiary basic amino groups. The acidic groups of DNA and the basic groups of the other substances interact, yielding various complexes of different stability. Streptomycin–DNA and spermine–DNA and atabrine–DNA complexes form precipitates. Spermine and streptomycin complexed with DNA are non-dialysable[8] through a 'Cellophane' dialysis membrane, indicating that these complexes are not readily dissociable.

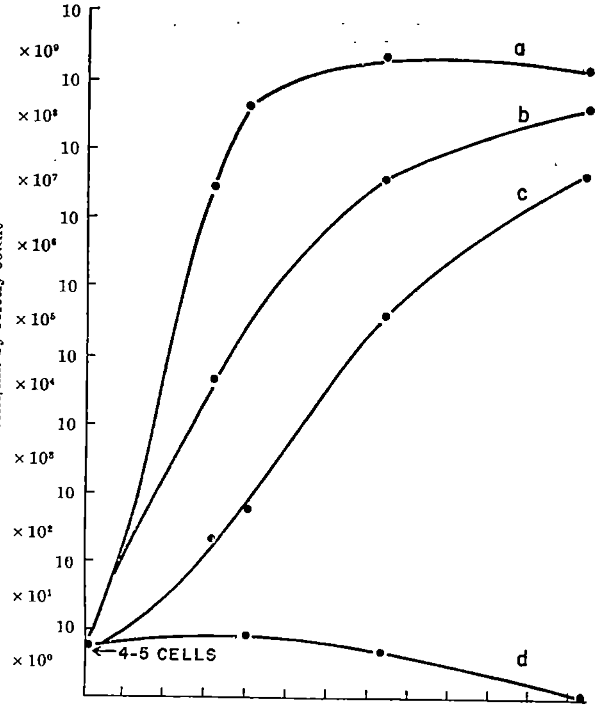

Fig. 1. *Staphylococcus aureus*, 3*A*. Growth rates in liquid media determined by colony counts by plating out aliquots at various periods of growth. *Inoculum size at 0 h:* 4–5 cells/ml. liquid medium. Curve *a*, control; curve *b*, in 100 μg/ml. sulphathiazole; curve *c*, in 100 μg/ml. atabrine; curve *d*, in the combined presence of 100 μg of sulphathiazole + 100 μg/ml. atabrine

Chemical nature of competition among the reactants. In view of the common basic groups in spermine, atabrine and streptomycin, competition among them for the acidic groups in DNA and in bacterial structure must be held in view. In the ribosomal system of *E. coli*, the incorporation of ^{14}C-valine is inhibited competitively by spermine and streptomycin[8]. The incorporation of ^{14}C-valine is inhibited 36 per cent by 100 μg of spermine and 92 per cent by 100 μg of streptomycin. The inhibition by streptomycin *per se* is reduced to 44 per cent if spermine is also present. This reduction of inhibition is independent of the order of the addition of the two competitors. The results may, perhaps, be interpreted to indicate that spermine has sufficient affinity for the common reactive sites of the system to be capable of reducing the inhibition by streptomycin to the level of its own inhibition. Relating this observation to the effect of their combined action on sensitive bacteria, one would ask the question whether or not streptomycin could displace spermine competitively from its complex with bacterial DNA and thereby nullify their combined action in the prevention of the emergence of resistant strains. Such an event, which would be expected to occur if streptomycin could have displaced spermine from its reaction sites in bacteria, was not observed.

Spermine with two secondary and two primary basic amino groups is very active. Spermidine with one secondary and two primary basic amino groups is less active. In contrast, putrescine and cadavarine with only two primary amino groups and agmatine with one guanido and one primary amino group are inactive. Generally, the basic property of the alkylamines is greater than that of ammonia and increases with the number of alkyls introduced. On this basis, the tertiary amino group will combine with the acidic groups of DNA more tightly than the secondary, and the latter more tightly than the primary, alkyl-amino groups. The inactivity of putrescine, cadaverine and agmatine is possibly due to their weaker binding and they are therefore readily displaceable by streptomycin. Supporting evidence is provided by Felsenfeld and Huang[9], who found that spermine binds more tightly to nucleic acids than putrescine.

The reports regarding the competitive displacement by streptomycin of acriflavine and acridine orange, from their combination with DNA[7], are of limited relevance to the results obtained with atabrine. Since the two primary amino groups in acriflavine and the two dimethylamino groups in acridine orange are attached directly to the aromatic nucleus, they may be considered as weaker bases than the primary, secondary and tertiary aliphatic amines. This difference arises from the basic character of the aliphatic radicals in contrast to the acidic character of the aromatic radicals. Their degree of affinities for DNA would, hence, be expected to be of different order. Streptomycin would readily displace aromatic amines but fail to displace the aliphatic amines or displace them with greater difficulty. Acriflavine or acridine orange would therefore compare to putrescine, cadaverine and agmatine in their failure to prevent the emergence of resistance. In contrast, atabrine, like spermine, because of its secondary and tertiary amino groups in the branched aliphatic side-chain, would be expected to complex DNA more tightly. In both the salts–glucose–casein hydrolysate or glucose broth medium no evidence of atabrine displacement by streptomycin with *E. coli* was observed. Nor were any observed with staphylococci growing in glucose broth. Occasionally, however, staphylococci grew in the salts–glucose–casein hydrolysate medium containing streptomycin and atabrine and 3 per cent phosphate salts. On reducing the phosphate concentration of the medium from 3 to 1 per cent growth failed to occur in the presence of streptomycin and atabrine during an incubation period of 163 h. Thus, streptomycin fails to displace atabrine in these systems.

An examination of the structures of the other antibiotics listed in Table 1 shows that none of them possesses amino groups comparable with those of streptomycin. They are therefore not expected to displace atabrine competitively. In fact, each of them together with atabrine prevented the emergence of resistant strains from the sensitive population of staphylococci.

When we consider DNA as the site of streptomycin action for the mediation of the resistance phenomenon we must consider also the question of whether or not the other drugs listed in the Tables function in a manner comparable with streptomycin. At present we do not have a direct answer to this question. However, on whatever site in the bacterial structure these drugs exercise an antibacterial effect, the fact remains that their resistance-inducing effects are registered lastingly in DNA. One may therefore conclude that the structural parts of a cell are in close communication with each other and exchange effects with DNA. (For supporting experimental data, see refs. 10 and 11.)

As stated previously on the possible role of spermine[2], atabrine by complexing with DNA prevents the resistance-inducing catalytic function of the drugs since neither spermine nor atabrine has any effect on the resistant state once it has come about.

Reduction of bacteria to a 'common status' by atabrine or spermine and the double role of a drug. Spermine or atabrine acting on various species of bacteria reduces them to a 'common status' with respect to the two major roles of drugs; first, as a positive catalyst, a drug mediates the emergence of the resistant strains from individual cells which possess potentiality for acquiring a resistance character; secondly, as a negative catalyst, a drug exercises an antibacterial role according to its specific mode of action. Spermine or atabrine, responsible for the production of the 'common status', prevents the first role of a drug. The abolition of the first role by atabrine or spermine lays open the normal cells and those with the potentiality to become resistant to the antibacterial action of drugs. This relationship may be better understood if we note the fact that when sulphathiazole was antagonized by PABA (Table 1, systems 28 and 29) its bacteriostatic or its atabrine dependent antibacterial role (Fig. 1) was eliminated, whereby a strain more resistant to sulphathiazole than the parent bacteria failed to emerge.

The above interpretation appears to find support in the fact that once an antibiotic, such as streptomycin, mediates the establishment of the resistance phenomenon in the atabrine- or spermine-free system, afterwards, the action of an antibiotic together with atabrine or spermine is no longer effective. In other words, the resistance-inducing role of an antibiotic must be blocked by atabrine or spermine before the bactericidal action of the antibiotic can take full effect on all the bacterial cells.

In the situations considered here, the role of spermine or atabrine may perhaps be compared with the inhibition of DNase action on DNA by atabrine, blocking the substrate regions to the active sites of the specific enzyme[6]. Thus, atabrine, by combining with DNA, renders it unyielding to changes by its specific enzyme. It may therefore be postulated that atabrine combining with bacterial DNA renders it unyielding to changes by an antibiotic, whereby the first role of the antibiotic fails to materialize and the second, the bactericidal role, takes full control of the situation, preventing the emergence of a resistant strain.

Conclusion

Three pertinent facts follow from the results reported here: (*a*) at the concentrations of drugs used, resistant strains emerge from an inoculum of 100 million normal cells; (*b*) the emergence of resistant strains from such an inoculum is prevented from occurring in the combination of a drug and spermine or atabrine; (*c*) the growth of the strains which are sub-cultured once in a drug *per se* is not inhibited by the combination of atabrine or spermine and that drug.

According to the tenets of the 'selection theory', a drug has no function in the catalysis of normal cells, or in causing them to experience the phenomenon of drug-resistance; it is said, also, not to have any action on the resistant cells which are assumed to be present in a normal population. The cells which have multiplied for the first time in the presence of a low dose of a drug must therefore have the same resistance character as those assumed to be present to begin with in an inoculum of normal bacterial population. On these bases the combination of a drug and atabrine, being incapable of preventing the multiplication of resistant bacteria, should permit the multiplication of the drug-resistant cells assumed to be present. The experimental data presented in the previous[1,2] and present investigations do not support these teachings of the 'selection theory'. Hundreds of inocula, each containing 100 million normal cells and capable of yielding resistant strains in the presence of drugs alone, failed to yield resistant strains in the combined presence of drugs and spermine or atabrine. On the basis of these facts, in the absence of spermine or atabrine, the drugs must have selectively catalysed the cells possessing potentiality into the resistant state. Furthermore, the results reported previously[10] show that sulphathiazole brings about mass transformation in the enzymatic composition of bacteria. The results with 25–50 cells as inoculum show also that this drug produces the resistant phenomenon (Fig. 1) in the absence of a selective process.

Atabrine has previously been shown to be an anti-malarial agent, and, since its very recent clinical trials in combination with antibiotics did not produce any undesirable effects, it is hoped that we are, perhaps, on the road to being able to cope with the medical aspect of the drug-resistance problems. It is also suggested that the principle outlined in this investigation may find application to non-bacterial systems, such as cancerous and viral systems.

This work was aided by a contract between the Office of Naval Research, U.S. Department of the Navy, and the University of Pennsylvania.

MORE FOSSIL PRIMATES AND OTHER MIOCENE MAMMALS FROM NORTH-EAST UGANDA

By Dr. W. W. BISHOP
Curator, Uganda Museum, Kampala

THE existence of fossiliferous Miocene strata in Uganda was first recorded in 1958. Since that year various investigations have been carried out and short accounts of the fossiliferous sediments and their contained fauna have appeared in *Nature*[1–3] and elsewhere[4,5].

In December 1963 and January 1964, with financial assistance from the Boise Fund of the University of Oxford, an expedition was organized, based on the Uganda Museum, Kampala. The aim was to carry out further detailed investigations of various sites at the two principal fossiliferous localities associated with the extinct and eroded volcanoes of Napak (34° 17′ E., 2° 5′ N.) and Moroto (34° 45′ E., 2° 32′ N.) in Karamoja District, north-east Uganda.

The expedition was fortunate to have the services for three weeks in January 1964 of Mrs. Sonia Cole. Dr. René Lavocat, Directeur de l'École des Hautes Études, Paris, also joined the field party for the same period. His experienced field identifications and enthusiastic pursuit of fossil rodents and primates contributed greatly to the success of the expedition. Field assistance was given by Mr. J. Nzabonimpa and other staff of the Museum and by Mr. F. Onyi and Mr. S. Rhemtulla, students at Makerere University College. I thank all these people, the Commissioner of the Uganda Geological Survey, Mr. and Mrs. Stevenson of Iriri, Karamoja, and others, for their assistance.

The following is a brief statement of the results of the expedition, placing on record a note of the fossils recovered, based on preliminary field identifications. A considerable fauna and a large corpus of stratigraphical information are now available in the Museum on the Uganda Miocene, and a monograph is in preparation which will include full details of the 1963–64 expedition and of earlier work.

Sediments

Table 1 records all the finds of fossils made by the expedition at the two main groups of localities which were investigated.

Group *A* embraces the sites: Napak I, IV, V, IX and X, from which the bulk of the mammalian fauna was recovered. As suggested previously[2], the excellent state of preservation of the fossils at these sites is the result of burial in calcareous, sub-aerial pyroclastic deposits, which are usually medium to fine tuff in grade.

Group *B* includes the sites Napak II and Moroto I and II. Here, owing to the deposits consisting primarily of gritty sediment resting on or near a surface of Pre-Cambrian rocks, the preservation is much less perfect. 'Small fauna' is virtually absent and a rather different ecological setting from that of Group *A* is suggested by those species which are preserved as identifiable fossils.

One of the aims of the expedition, in addition to adding to the faunas from different sites, was to relate the fossils as clearly as possible to their parent deposits by undertaking archæological-type excavations. From these, details of the lithologies and the mode of occurrence of the fossils were obtained with the view of reconstructing from the stratigraphical and palæontological evidence the nature of the local environment at each of the faunal sites.

As an adjunct to such palæo-ecological investigations it was hoped to establish a reason for the 'fossiliferous patches' which occur within the tuffs. Three such bone concentrations were noted during the 1961 expedition[2], and a further 'patch', Napak IX, was located in 1962 by the Brathay Exploration Group expedition to Uganda[6]. Again during the present expedition the bulk of the pieces of mammalia collected came from the four Group

* Two individuals represented by 56 fragments.

A sites, Napak I, IV, V and IX, which range from 50 ft. to 150 ft. in diameter. Few fossils were found from the outcrops of the tuffs which are the lateral equivalent of those at the fossil sites, despite deliberate and careful search over the mile or more of exposure revealing apparently identical lithologies. The problem was to try to establish whether the concentrations represented a biocœnosis, or life association, of the animals recorded by the fossil evidence, or a death assemblage (thanatocœnosis).

In a pyroclastic deposit it is tempting to invoke some occurrence recalling the destruction of Pompeii or suggesting the former existence of a fumarole emitting poisonous gas. However, the virtual absence of complete skeletons or partially articulated limbs as revealed by excavation makes this unlikely. In addition the occurrence of signs of gnawing and chewing on many of the fossil bone fragments, together with the very high proportion of skulls, teeth and jaws in relation to post-cranial fragments (an average of 14 per cent of total finds for all the Group *A* sites (Table 1), suggests the action of predators in devouring the carcases and scattering the inedible remnants prior to their gentle stratification by ash from the next explosive phase of volcanic activity.

The life association might possibly have arisen from concentration of animals as dictated by the presence of some necessity such as a water-hole or salt-lick. With a high percentage of primates it was just conceivable that, even in rocks as early as Miocene, the fossil concentrations represented bone accumulation following a successful hunt. The results obtained have shown that although the fossils originate as part of natural death assemblages their secondary concentration in patches arises from different causes.

The method of approach was to clear surface vegetation and then to rake and brush all loose detritus on the fossil sites into small heaps. This unconsolidated material was then passed through one or more of three grades of large sieve. The meshes used were 1 mm, 2 mm and 4 mm. The yield of fossils from the sieves reflected the richest parts of a site much as in geochemical prospecting.

Trenches were then opened at the most promising localities, to expose the sediments and fossils *in situ*. The excavations revealed that the fossils in the rich patches were not derived from a single 'bone bed' but in every case from several thin and sparsely fossiliferous layers separated from each other by a few feet of barren tuff. These breaks in deposition showed various degrees of soil formation and frequently had casts of horizontally ramifying roots of fossil vegetation. At Napak I six such horizons occurred within 35 ft. of tuff. Although the yield of fossils from each horizon was small, identifiable and apparently identical rodents were recorded from all the levels. Again, at Napak IV, where the most extensive excavations were carried out, three similar discrete horizons, which yielded fossils consistently yet sparingly, were located within 25 ft. of sediment.

An important factor contributing to the patches appeared to be the presence of a suitable present-day catchment area in association with the fossiliferous layers to enable a secondary concentration of fossils to be built up through gradual etching-out by processes of weathering and erosion acting over a long period of time.

At Napak IV the catchment area is provided by a basin-like dry valley with a restricted outlet. At Napak I, V and IX (and also at X where few Mammalia but numerous fruits were obtained) the catchment area is provided by flat benches or berms, underlain by horizontal resistant strata, occurring on the ends of spurs. The specimens derived from the thin fossiliferous horizons on the steep slopes are concentrated on the 'flats' at their bases.

One other variable which seems to contribute to the resistance of the fossils to weathering, which is essential for the natural but gradual etching-out of well-preserved specimens, is the immediate chemical environment or sedimentary matrix of the fossil.

In thin section the tuffaceous matrix in which the fossils are embedded can be seen to possess a calcite cement. Because of recrystallization it is virtually impossible to be certain of the initial composition of the ash which blanketed the original bones. However, chemical analyses show that at present the fossil bones, tusks and teeth have a CaO content ranging from 44 to 49 per cent, while the tuffs forming the matrix range from 37 to 40 per cent. A thin layer of calcite frequently encrusts the fossils and binds them together as coherent specimens even when the bone or tooth enamel itself exhibits numerous cracks.

At all the fossiliferous localities veins of secondary calcite occur and in places the tuffs have been sufficiently calcified to warrant their being referred to loosely as 'limestones'. Some joint planes are marked for short distances by bands of calcareous tufa up to three-quarters of an inch in thickness. At Napak IV immediately above the fossil site and centrally situated in relation to the fossiliferous area, a former spring-eye is marked by a 'motor tyre' structure of travertine. There seems little doubt from the nature of the upper surface of the travertine that the spring was a recent feature. However, as a result of movement of calcium-rich surface and ground water near the spring-eye, the tuffs are intensely calcified and all joints and cracks are filled with calcium carbonate.

It seems probable that the deposition of travertine at Napak IV and possibly the action which gave rise to the bands of tufa at other localities, although of comparatively recent age, gave to the fossils that extra durability which enabled them to survive on erosion to become secondarily concentrated in their respective catchments. A few of the fossils which were recovered by excavation had escaped secondary calcification. When this was the case the bones were exceptionally fragile and required very careful removal and preservation owing to their cracked condition. Such fragile specimens would become comminuted while in the soil instead of surviving to lie on the surface.

It is suggested that, in the absence of secondary calcification plus a suitable catchment, the tuffs would appear to be largely unfossiliferous. The fossiliferous patches reflect not only a suitable medium for burial and initial fossilization but also a suitable chemical environment and physical catchment to ensure the re-emergence and concentration of recognizable specimens for the palæontologist.

Fauna

Mammalia. During six weeks' field work a total of 3,504 mammalian specimens was collected, of which 417 pieces were parts of skulls, teeth and jaws. Although many of the post-cranial pieces recorded as 'better' bones in Table 1 are well preserved, the extent to which they are assignable to genera or species is variable. Thus comparison of numbers of different groups present at each site has been limited to the more readily and consistently identifiable skulls, teeth and jaws.

Although 1,021 mammalian specimens were recovered from the Group *B* basal grits, only 75, or 7 per cent, were fragments of skulls, teeth and jaws. Of these, broken-up fragments of molars and tusks of Proboscidea, chiefly representing *Trilophodon angustidens* with a few fragments of *Dinotherium*, account for almost 50 per cent. Teeth of other mammals occur only sparingly at these sites, but the presence of rhinocerotids and anthracotheres is of interest as both are rare at Group *A* sites. Carnivore remains have not been recorded previously from the Group *B* localities, but a tooth from Napak II recovered during the recent work appears attributable to *Pterodon*, which in the form of *Pterodon africanus* has been recorded from Napak I. The small fauna of primates, insectivores and rodents is virtually absent from Group *B* although single rodent incisors were recorded for the first time at Napak II and Moroto II. The remains of large primates recovered from Moroto II are discussed below.

In sharp contrast to the assemblages at the Group *B* sites is the overwhelming abundance of rodents at the Group *A* sites where they comprise 218, or 64 per cent, of the total of 342 skulls, teeth and jaws collected. However, there is considerable individual variation in the percentages of rodents from site to site. At Napak IV the 158 rodents represent 74 per cent of the total, and at Napak I 75 per cent, but at Napak V the percentage drops to 40 per cent and again to 16 per cent at Napak IX.

Artiodactyls also show considerable variation in relative abundance with 32 per cent of the total at Napak V falling to 16 per cent at Napak IX, 14 per cent at Napak I and 7 per cent at Napak IV. Where the total number of skulls, teeth and jaws collected at a site is small, some doubt may exist as to whether the observed differences are significant. However, if reference is made to the 1961 collections from the same sites a remarkably similar picture is presented. At that time rodent percentages were also highest at Napak IV with 84 per cent and artiodactyls at Napak V with 34 per cent of the total.

Proboscidea are more difficult to assess, as both tusks and molars are easily fragmented on exposure to weathering. Thus a single individual may be represented in the collections by numerous fragments. This appeared to be the case at Napak IX, where 16 fragments of proboscidean teeth were collected in a total of 26 pieces. At Napak I, where numerous fragments of Proboscidea have been collected previously, only two more were found in a total of 44 pieces. By contrast another 33 rodents were recovered, presumably because the smaller rodent fragments are more difficult to see. Rodents as a whole are so numerous that they offer the best basis for comparison between localities differing slightly in age or ecological setting, with histograms illustrating the nature of each fauna as in micropalæontology.

Primates, which are normally reticent candidates for fossilization, have been consistently present at four of the Group *A* sites. At Napak IV they were next in abundance to rodents and the 18 specimens constituted 8 per cent of the total. At Napak V, 7 more specimens were recovered comprising 12 per cent of the total compared with 14 per cent in 1961. The primate finds are dealt with in more detail below.

The mammalian fauna, so far identified from all the Group *A* sites at Napak, bears a remarkable similarity to the genera and species occurring in the assemblages from Rusinga and Songhor in Kenya, although the relative abundance of many of the species may later be shown to differ.

Lower Vertebrates and Invertebrates. A total of 1,147 non-mammalian fossils was collected comprising reptiles, birds, fish, millipedes, gastropods, fruits and coprolites. The numbers in each group vary tremendously as shown in Table 1, with reptiles by far the most numerous with 796 pieces and land snails next in importance with 163 individuals. The non-mammalian fossils help to emphasize differences in the nature of the assemblages and in the type of preservation at the two groups of sites. Reptiles are most abundant at the Group *B* sites, where they consist chiefly of chelonian scutes, while the land snails are entirely restricted to Group *A*.

At the Group *A* sites reptiles are comparatively insignificant in numbers compared with mammals (a total of 112 pieces compared with 2,482). At these sites the principal reptile remains are snake vertebræ, lizard scutes and chelonian fragments. The millipedes and fruits are few in number and restricted entirely to Group *A*, as for the most part are the bird remains, while fish and coprolites have been recorded only from Group *B*.

There seems little doubt from the Group *A* faunal evidence of the sub-aerial nature of the tuff environment. The Group *B* fauna suggests a waterside setting.

Primates. Between 1958 and 1963 nineteen fossil fragments identifiable as primate were recovered from the Napak Group *A* localities and eight fragments from Moroto II [1-3]. The success of the 1963–64 expedition in this field can be seen from the fact that another 28 individual specimens representing primates (26 parts of skulls, teeth and jaws (Table 1)) were collected at Napak. At Moroto II, 56 fragments were recovered representing parts of probably not more than two individuals.

The majority of the finds at Napak were from site IV, which yielded a total of 18 pieces of skulls, teeth and jaws. With the exception of *UM.P.* 64–01, a right upper M^1 of *Proconsul major*, the majority of the finds were of small primates[6].

The most complete specimen from this site *UM.P.* 64–02 is an undeformed palate and snout which seems attributable to a small species of the hylobatine genus *Limnopithecus* or *Pliopithecus* (Simons has recently proposed that the genera *Limnopithecus* and *Pliopithecus* can no longer be considered distinguishable[7]).

The specimen *UM.P.* 64–02 is the most complete single specimen so far recovered of a small representative of this genus. Although still not fully developed from its block of matrix it can be seen to retain on the left side M^1, M^2 and M^3 and the root of the canine, and on the right side, P^3, P^4, M^1, M^2 and M^3. The face is present as far as the lower portion of the left orbit. The remaining site IV finds are a variety of small fragments and isolated primate molars, canines and incisors of varying sizes. Some are larger and some smaller than appropriate teeth of the *Limnopithecus* specimen *UM P.* 64–02 referred to here.

Although most of these specimens were recovered by sieving the surface detritus, seven specimens were found *in situ* in two small excavations. The density of primate remains is remarkable as the whole of Napak site IV measures only 45 ft. by 50 ft., while the excavations are 4 ft. by 9 ft. and 5 ft. by 8 ft., respectively, and were dug into bands of tuff less than 1 ft. in thickness.

Napak V yielded seven specimens all from the surface detritus, including five single teeth of small primates, a lower premolar of *Proconsul*, and an upper right lateral incisor with broken crown, which is also ascribed to *Proconsul*. Napak IX yielded two specimens, a fragment of right mandibular ramus of *Limnopithecus* containing M_2 and M_3, and the head of a femur possibly of the same genus. The four Napak sites have now yielded in 6 years a total of 45 parts of primate skulls, teeth and jaws representing fossil Pongidae, Hylobatinae, Galagidae and possibly Cercopithecidae.

By contrast with the variety of forms and the number of individuals recovered from Napak, the site at Moroto II is remarkable for the fact that although 64 primate fragments have been recovered they probably represent not more than three individuals of the single species *Proconsul major*.

A brief history of the finds at Moroto II is as follows: In August 1961 at the end of an expedition to Uganda from the University of Glasgow, Bishop and Whyte found the new site Moroto II which yielded, following only a brief investigation, two primate fossils. These were part of a left maxilla without teeth (*UM.P.* 62–11), and a fragment of a massive right mandibular ramus (*UM.P.* 62–10).

In December 1961 Prof. D. B. Allbrook was able to visit the new Moroto site with a party of students from the Department of Anatomy, Makerere University College. They found a large piece of the right maxilla and two adjoining fragments of the original specimen *UM.P.* 62–11, together with a single left upper canine (*UM.P.* 62–12), and two small mandibular fragments probably part of

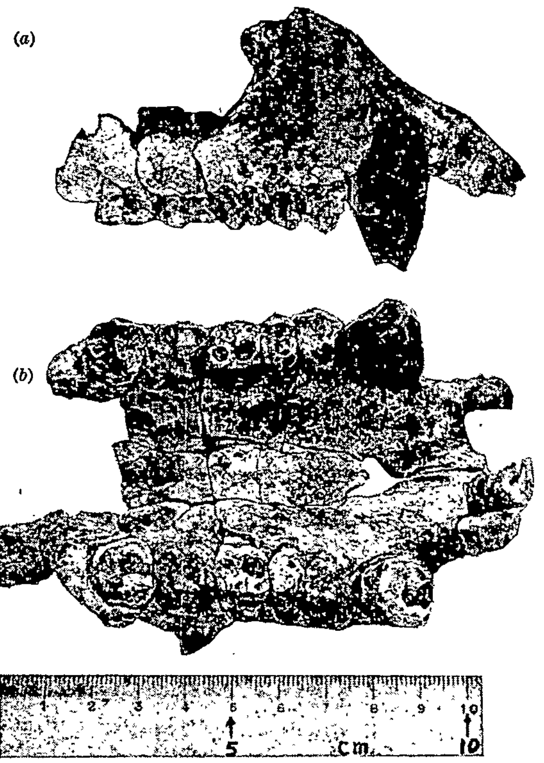

Fig. 1. The new palate *UM.P.* 62–11 from Moroto II. (*a*) Lateral view; (*b*) palatal view

UM.P. 62–10. All this Moroto II primate material and another seven pieces found between 1958 and 1962 at Napak (*UM.P.* 62–03 to *UM.P.* 62–09) have been attributed by Allbrook and Bishop to the species *Proconsul major*[3].

Despite a time-lag of 2·5 years since the discovery of the first primate fossil at Moroto II the recent expedition has now recovered, by sieving and excavation at the original site, 56 additional pieces, of which 49 seem to belong to the palate *UM.P.* 62–11 and a further 7 with the fragmentary mandible *UM.P.* 62–10.

It is not proposed to describe the new material in any detail here as a full account of all the Uganda primate fossils is in preparation. However, as the palate *UM.P.* 62–11 is the most complete upper dentition known of a 'Lower' Miocene ape, apart from the classic Rusinga skull of *Proconsul africanus* discovered by Dr. L. S. B. and Mrs. Leakey, a preliminary account of the Moroto II specimen is given here.

When originally described, the specimen only had the crowns of three teeth, right P^4 and M^1 and left M^2 (ref. 3, Fig. 1). An additional 14 pieces have now yielded at least parts of the crowns of another 12 teeth.

Details of the teeth are given in Table 2. The molar–premolar series is now complete on both sides of the palate although a small chip of enamel is missing from the anterior/lingual corner of the right M^2 and another chip from the lingual portion of left P^3. The left canine is broken off and missing just above the base of the enamel, but the right canine is almost complete although reconstructed for about 7·0 mm above the alveolus and lacking the tip of the crown (Fig. 1*a*). Both left incisors are entire, but the right lateral incisor although complete in the crown is lacking a portion of the root for 3·0 mm above the alveolus. The sixteenth tooth, the right medial incisor, was lost during the life of the creature and the alveolus in the fossil is partially filled with bone. Both lateral incisors show elliptical wear facets from contact with the lower canines.

Table 2. TEETH OF SPECIMEN *UM.P.* 62–11

	Left			Right		
	A.P. (mm)	*Tr.* (mm)	*Ind.*	*A.P.* (mm)	*Tr.* (mm)	*Ind.*
M^3	12·7	13·5	106	13·0	13·7	105
M^2	12·9	13·3	103	13·0	13·4	103
M^1	11·7	12·0	103	11·0	12·0	109
P^4	7·7	14·3	186	7·5	14·0	187
P^3	9·8	13·9	142	9·9	13·9	140
C	19·0	15·5	82	18·0	15·0	83
I^L	9·7	8·2	85	9·7	8·1	84
I^M	8·7	10·3	118	—	—	—

Eleven more fragments of the palate and lower face have been added to the specimen, while another seven fragments comprising the nasal area as far as the base of the orbit have been reconstructed into one piece. This specimen joins on to the reconstructed snout and palate at one point but is not included in Fig. 1*a*. The complete specimen has been reconstructed from a total of 36 fragments. Another 17 pieces undoubtedly belong to the same specimen but cannot be fitted into place.

Although the specimen has been reconstructed from so many fragments the bones are massive and all the breaks are sharp and unabraded, which suggests that the specimen had only just eroded out and that it broke up immediately on doing so. The jagged edges of adjoining pieces fit together with a perfection which prevents errors in reconstruction. As the specimen is free from post-mortem deformation the profile of the muzzle and the morphology of the palate can be seen perfectly and recall strongly those of maxillary specimens of *Proconsul africanus* from Kenya, although the Moroto II specimen is much larger. (Average length of cheek teeth row in *P. africanus* 35 mm, and in *UM.P.* 62–11, 54·6 mm.)

Specimen *UM.P.* 62–10 is now represented by ten fragments although only two can be joined together. There is little hesitation in associating them as originally part of one individual, as the bone has a characteristic purple-brown patination and the fragments were all recovered from a surface area 8 ft. in diameter. This location is 40 ft. away across an erosion gully from the spot at which the parts of *UM.P.* 62–11 were found but lies on the same stratigraphical horizon.

Four of the specimens are only broken pieces of bone and three others retaining parts of the roots of teeth are too fragmentary and abraded to warrant further comment here. One piece shows the broken-off root of a large canine tooth still surrounded by massive but rather worn bone. The portion of canine is 27·0 mm in length and measures 17·0 mm by 13·0+ mm at its widest part.

The fragment of massive right mandibular ramus *UM.P.* 62–10, described by Allbrook and Bishop[3], has now been joined to another mandibular fragment containing the very broken crown of M_1 and completing the anterior portion of M_2. The measurements of the shattered crown of M_1 are *A.P.* 10·0 mm, *Tr.* 10.0 mm, and of the root of M_2, *A.P.* 11·4 mm, *Tr.* 12·7 mm.

Although the identifiable fragments of *UM.P.* 62–10 and 62–11 represent lower and upper dentitions respectively of a large fossil ape, the separation of the two finds into two subsites in the same gully, their different preservation, and the fragmentary nature of *UM.P.* 62–10 make it doubtful if they represent parts of one individual. It is suggested that two individuals are possibly involved with the isolated upper canine *UM.P.* 62–12 probably representing a third.

Throughout this paper the Moroto II specimens have been assigned to the species *Proconsul major* as defined by Le Gros Clark and Leakey[6]. The reasons for the original designation of *UM.P.* 62–11 as belonging to this species were set out at some length by Allbrook and Bishop[3].

However, it may be added that Simons[7] has recently directed attention to the proliferation of genera in Miocene primates and has suggested that the existing material should be assigned to only three or four genera. *Proconsul* and *Dryopithecus* are included in these four, but it is worthy of note that Simons makes reference to "the probability that *Proconsul* cannot be separated generically from *Dryopithecus*".

In the face of such views, together with such considerations as the variability of dentition and skull morphology in living pongids, and the range of variation in fossil specimens owing to sexual dimorphism, it seems premature to do more than refer the specimen to the existing species *P. major* at this stage. It is unfortunate that the bulk of the Kenya specimens of *P. major* are mandibular fragments or from lower dentitions, with the exception of two isolated upper second molars, while the majority of the Uganda specimens are by an odd coincidence maxillary fragments or upper teeth. The similarities between the two upper second molars from Kenya (5·381′49 and *CMH.* 35(5)) and the relevant teeth from Napak and Moroto have been referred to previously[3].

The mandible fragment (*UM.P.* 62–10) from Moroto II is remarkably similar to the relevant fragment of *Proconsul major* recovered from Songhor in Kenya. Although it has already been shown that the upper and lower dentitions from Moroto II cannot safely be considered as belonging to the same individual, their general similarity in size makes it probable that they belong to the same species. Until it can be shown beyond doubt that two apes of almost identical size and similar morphology which lived and died close together at Moroto II nevertheless belonged to separate species, it seems preferable to apply Occam's Razor and assume that they were two individuals of the same species.

A similar argument can be applied at Napak, as molars morphologically identical to those of *UM.P.* 62–11 from Moroto II have been recovered from Napak I, Napak IV and Napak V. Table 3 compares details of the upper first and second molars recovered from Napak and Moroto. The additional fragments of the canines from the palate *UM.P.* 62–11 confirm in size and morphological similarity the comparison which was made by Allbrook and Bishop[3] between the six upper canines from Uganda. These are *UM.P.* 62–11 and 62–12 from Moroto II and from Napak I (*UM.P.* 62–03) and Napak V (*UM.P.* 62–04 and 05). The broken right lateral incisor from Napak V has dimensions *A.P.* 9·8 mm, *Tr.* 7·9 mm and an index of 81 which compares closely with the lateral incisors of the Moroto II specimen. It also has a similar elliptical wear facet.

Table 3. VARIOUS UPPER FIRST AND SECOND MOLARS FROM UGANDA

Details			*A.P.* (mm)	*Tr.* (mm)	Index
Moroto II	*UM.P.* 62–11	Left M^1	11·7	12·0	103

Conclusion. Fossil remains of *Proconsul major*, an ape exhibiting slight variations in dentition and morphology, similar in range to those to be observed in the modern gorilla, have now been recovered from four separate sites in Uganda. These are Moroto II (2 or 3 individuals), Napak I (2 or more individuals), Napak IV (1 individual) and Napak V (at least 2 individuals). From Kenya the species is known from Songhor and Rusinga, and the general faunal similarity of the Napak assemblage to the faunas of these two sites has already been commented on.

Simons suggests that detailed comparisons may show material virtually identical with the species *Proconsul major* of East Africa to occur among the Miocene 'Siwalik' apes of India and Pakistan.

In ending this article on the new material from Uganda perhaps one cannot do better than to echo part of a sentence from the pen of Prof. T. N. George. It is to be hoped that more new genera and species of Miocene primates will not be established which are based on fossils "differing morphologically in only minor ways from specimens already described"[9].

Thus the Moroto II palate is ascribed to *Proconsul major*. With the other new finds from Uganda it should greatly assist comparative investigations of East African, European and Siwalik material. Until these are carried out, *Dryopithecus* and *Proconsul* seem best viewed, again as suggested by Prof. George, as variable "collateral representatives of the generalized radical from which both the pongids and hominids sprang".

Radiometric Dating

During the 1961 expedition a series of specimens collected from Napak and Moroto was sent for ^{40}K/^{40}Ar dating to Drs. J. F. Evernden and G. H. Curtis, of the University of California, Berkeley, and Dr. P. Damon, of the University of Tucson, Arizona.

I thank Dr. Damon for details of the first determination. This is for biotite from a sample of tuff within the fossiliferous sediments at Napak I. The apparent age obtained was 19 ± 2 million years. (Full details of this determination together with results for other samples will be given as soon as available.)

Dr. Damon writes: "The potassium content indicates that the biotite has not been seriously perturbed by ion exchange and the retentivity should be good in the absence of subsequent reheating. The biotite flakes and books were ragged in some cases, rounded in others and of different sizes. The possibility has to be borne in mind of contamination by older biotite from basement rock. A large error is assigned because there was only enough biotite for a single analysis and the air correction was two-thirds of the total argon".

The age of 19 ± 2 million years would fall within the Burdigalian which agrees with the generally accepted faunal age of the East African 'Lower Miocene'. It would also be in keeping with the ^{40}K/^{40}Ar age of 14 million years quoted for the Fort Ternan fauna[10]. However, an age of 15·3 ± 1·5 million years has been recorded by Evernden and Curtis as their best date for tuffs on Rusinga Island[7]. As this date refers to horizons older than those which yielded the 'Burdigalian' fauna from Rusinga a problem is raised by the short period of time available for the development of a virtually new series of forms at Fort Ternan in all the faunal groups, compared with those occurring in the 'Lower Miocene' at Rusinga, Koru and Songhor and at Napak.

All the differences between the typical 'Lower Miocene' fauna and the contrasting assemblage at Fort Ternan are unlikely to be ecological, and it would seem that the Napak date appears more realistic at present from the palæontological evidence. However, it must be emphasized that these are merely the first results from radiometric dating of fossiliferous Tertiary strata in East Africa, while faunal correlations between Europe and Africa, based on land mammals, are somewhat speculative.

NATURAL RUBBER RESEARCH

A CONFERENCE to mark the silver jubilee of the Natural Rubber Producers' Research Association (NRPRA) was held at St. John's College, Cambridge, during April 7–9, and was attended by more than 150 delegates from the universities and industries of many countries.

The Association was formed in 1938 to meet the need for research into the nature and properties of natural rubber. Together with its sister organization, the Rubber Research Institute of Malaya, it is financed by and operates under the ægis of the Malayan Rubber Fund Board in Kuala Lumpur. It thus represents an unusual, if not a unique, variation in the present pattern of technical assistance, being a scientific foundation supported by a developing member of the Commonwealth in the territory of an industrial member—to the reciprocal benefit of both. In setting up the Association it was recognized that rubber technology needed to be based on a firmer scientific foundation and that the time had come when it was necessary to do something about it. These times were recalled by Sir Harry Melville in a plenary address in which he traced the achievements of the Association over the past twenty-five years. Sir Harry pointed out that doubts existed in the 1930's as to whether rubber was really a high molecular weight polymer at all and that then there were still supporters of the 'micellar' or association theory of natural polymers, according to which the polymers consisted of small molecules associated by unusually strong residual valency forces into aggregates or micelles.

The problem that faced the British Rubber Producers' Research Association, as it was then, was the introduction of a rationale into the technology of making satisfactory rubber materials and components. To achieve this end it set out on investigations which were to bring clearly into focus the molecular make-up of natural rubber and similar polymers and the physical background of their unique mechanical properties. In describing the prominent contribution of NRPRA to the development of polymer science, Sir Harry directed particular attention to the mechanism of vulcanization, oxidative degradation and rubber elasticity.

Stimulating plenary addresses were also given by Prof. Herman Mark (Brooklyn) and Prof. James Bonner (California). Prof. Mark described recent advances in polymer chemistry with special reference to new types of co-polymers, including 'ladder' polymers. He stated that the recent advent and commercial production of so-called 'stereo' rubbers had led to great interest in, and fuller understanding of, the mechanism of ionic polymerization. The use of ionic catalysts offered the possibility of producing a much wider range of materials than could be made with free radical catalysts and unusual combinations of monomers had now become possible. Of special interest were co-polymers which exhibit flexibility and stability at extremely high temperatures, and Prof. Mark demonstrated the outstanding high-temperature properties which could be achieved with ladder polymers.

Prof. Bonner discussed some of the problems likely to arise in future investigations of the control mechanisms in rubber biosynthesis. When latex was withdrawn from the tree, enzymes and co-factors essential for the regeneration of rubber were also removed. This drastic disturbance in the physiological balance of the laticiferous tissue might mean that the rate of enzyme synthesis was of particular importance in determining the yield of rubber from a tree.

The conference sessions were devoted to tw
topics: the ultrastructure and metabolism of
latex, and the chemical structure and mechani
perties of vulcanized rubber. Great interest was s
work on the mechanism of rubber biosynthesis.

carotenoid synthesis.

The composition and stability of the lutoi
fibrils were discussed in a paper by Dr. B. G.
(NRPRA). One of their most interesting fe
the reversible break-down and re-formation of t
fibrils under suitable conditions of temperature

Temperatures below 0°C and *p*H values close to the isoelectric point of the protein favour the reassembly of the fragments into long microfibrils. The mechanism of this process aroused considerable discussion, centring mainly on the question whether separation of the double helix into single strands was a necessary preliminary to both break-down and re-formation of the microfibrils. Dr. Audley stated that the metabolic function of the microfibrils and the lutoid particles themselves was not known, but that neither contained ribonucleic acid.

Three papers were presented dealing with different aspects of rubber biosynthesis. Dr. R. G. O. Kekwick (Birmingham) discussed some of the earlier stages in the biosynthesis, with particular reference to the roles of acetate and mevalonate and the influence of ATP on their incorporation into rubber. An unexpected finding was that ATP at moderately high concentrations retarded the incorporation of acetate but not of mevalonate, suggesting that ATP-dependent side reactions might be taking place involving, as substrate, one of the intermediates between acetate and mevalonate.

Dr. D. Barnard (NRPRA) recalled that the work of Bloch, Lynen and others had established that the 'active isoprene' derivative utilized in the build-up of terpenoid chains is isopentenyl pyrophosphate. For terpenoids containing an isopropylidene end group the chains are initiated by dimethylallyl pyrophosphate, formed from isopentenyl pyrophosphate by an isomerase enzyme. So far, this enzyme has not been detected in rubber latex. However, Dr. Barnard described experiments showing that incubation of a mixture of dimethylallyl pyrophosphate and isopentenyl pyrophosphate with the (rubber-free) aqueous phase of latex resulted in the formation not of rubber but of *trans-trans*-farnesyl pyrophosphate. This product was shown to have a marked inhibitory effect on the incorporation of isopentenyl pyrophosphate into rubber. Dr. Barnard pointed out that the presence in the aqueous phase of latex of enzymes capable of forming low-molecular-weight *trans*-terpenoid compounds suggested a likely control mechanism for the utilization of isopentenyl pyrophosphate in latex.

Dr. B. L. Archer (NRPRA) described recent work on the biosynthesis of rubber (*cis*-1,4-polyisoprene) in whole latex. The incorporation of isopentenyl pyrophosphate into rubber *in vitro* appears to occur exclusively at the surface of existing rubber particles, at a rate proportional to the surface concentration of enzyme as calculated from the Langmuir adsorption isotherm. The addition of dimethylallyl pyrophosphate increased the rate of incorporation of isopentenyl pyrophosphate into rubber, provided that the farnesyl pyrophosphate synthesizing enzyme in the aqueous phase of the latex was first removed, thus indicating that rubber molecules can be formed *de novo* from dimethylallyl pyrophosphate in the presence of a rubber surface. Dr. Archer also described work carried out in collaboration with Dr. G. Popjak and his colleagues, in which the incorporation of 2-(^{14}C)-4-(^{3}H)-mevalonate into rubber had been studied. The availability of this material in two stereoisomeric forms had enabled the authors to prove that in the formation of rubber the elimination of a proton from the α-carbon atom of isopentenyl pyrophosphate was completely stereospecific. Furthermore, stereospecificity was in the opposite sense to that previously found by Popjak for the formation of *trans-trans*-farnesyl pyrophosphate in liver systems.

A speculative, but stimulating, paper on the role of rubber in plant metabolism was given by Dr. F. J. Bealing (NRPRA), whose thesis in essence was that rubber formation provides a mechanism for the anaerobic reoxidation of the TPNH produced (mainly) by operation of the pentose cycle. This reoxidation occurs during the reduction of β-hydroxy-β-methylglutaryl-coenzyme *A* to mevalonic acid, and the subsequent formation of rubber was considered by Dr. Bealing to be the means of converting relatively large quantities of the soluble acid to a metabolically inert product. However, this transformation requires the consumption of three molecules of ATP per molecule of mevalonate, and a lively discussion was held on the sources and availability of ATP in rubber latex.

The symposium on the chemical structure and mechanical properties of vulcanized rubber was opened by Prof. G. Gee (Manchester), who discussed some recent developments in the field of rubber elasticity. The main features of rubber elasticity are accounted for by a model consisting of a set of random flight chains linked together into a network. Corrections are needed for the small volume change which accompanies elongation and results in an increase of energy. Recently, account has also been taken of the effect of the energy difference between rotational isomers in the main chain. Separation of these two factors has been achieved experimentally by thermoelastic measurements at constant volume. There still remain small discrepancies between theory and experiment; these may arise from the excluded volume problem in a real chain.

In a paper dealing with the strength of rubbers, Mr. A. G. Thomas (NRPRA) pointed out that many apparently different types of mechanical failure were based ultimately on a common physical process, namely, the propagation of a tear in the rubber. This had led to the development of a unifying way of describing the strength of rubber in which the energy required to create unit area of new surface (the 'tearing energy') was a parameter of fundamental significance. The tearing energy was generally much higher than ordinary surface energies because, in the case of rubber, the energy associated with stress concentration at the tip of a flaw could be readily dissipated throughout the surrounding volume. By means of the tearing energy, cut growth could be theoretically related to fatigue and flex-cracking behaviour; the theory postulated flaws of ascertainable size as initiating this type of failure.

Dr. A. Schallamach (NRPRA), talking on tyre wear, first stressed the importance of the elastic properties of tyres on the amount of sliding, and therefore abrasion, in the area of contact with the road. These effects are as relevant to wear as the abrasion resistance of the tyre tread. The mechanism of abrasion depends on the nature of the road, and at least two processes can be distinguished. On a sharp pointed surface, tensile failure predominates; on smoother surfaces, fatigue governs the rate of wear. In practice, both processes come into operation, and relative ratings depend on the severity of service.

The chemistry of vulcanization was considered in a paper by Dr. C. G. Moore (NRPRA), who first outlined the different experimental approaches to this complex subject, including the use of model olefins and of 'chemical probes' to detect specific groups in the vulcanizates. Such methods had led to a much better understanding, in recent years, of the chemistry underlying the vulcanization process. As a result, an explanation could now be given of the way in which the nature of the vulcanizing agent affected the structure of the initially formed cross-links between the rubber chains, and of how these cross-links influenced the subsequent chemical reactions occurring during vulcanization and in service. Dr. Moore pointed out that this knowledge represented an important advance in our ability to design the type of vulcanizate best suited to particular industrial applications.

Dr. Cunneen stated that the chemistry of the oxidative ageing of natural rubber vulcanizates had been studied at the NRPRA ever since its formation. The work was initially carried out by Dr. Bateman, Dr. Bolland, Dr. Farmer and Prof. Gee. Their researches led to explanations for the characteristic features of olefine autoxidation, and showed that oxidation proceeded via a free radical chain mechanism that is now well-known.

These studies were later extended to simple organic sulphur compounds which structurally resemble the sulphurated groups present in vulcanizates, and to mixtures of sulphur compounds and olefines. The chemical results, in conjunction with those obtained directly on the ageing of vulcanizates by the technique of stress relaxation, have explained many of the hitherto puzzling features of ageing. Dr. Cunneen indicated that attention is now concentrated on the scission reactions which occur during ageing, and which must be primarily responsible for the loss of physical properties.

In a final lecture, Dr. L. Mullins (NRPRA) drew together the work which had been described in previous lectures on both the determination of detailed differences in vulcanizate structure and the understanding of mechanical properties, and he attempted to establish the present position with regard to relationships between structure and properties. He traced how the mechanical behaviour of vulcanized rubber depends not only on the chemical constitution of the base rubber and the density of cross-links introduced by vulcanization, but also on the type and distribution of cross-links and on changes produced in the base polymer during vulcanization. He showed how at least a qualitative explanation for the effects of each of these factors on the elastic and strength properties could now be advanced and how detailed differences in vulcanizate structure had important effects on chemical properties as reflected by ageing.

Closing the conference, Dr. Bateman (Malayan Rubber Fund Board) said that the rubber tree was one of the supreme agricultural colonists of all time. Unknown in the Far East eighty years ago, it now covered ten million acres and produced more than two million tons of rubber worth £400 million a year and supported, directly or indirectly, millions of people. Referring to the past work of the NRPRA, he applauded the decision of their first Board to concentrate on laying bare the underlying science of rubber technology. The immense impact of this course of attack and the transformation in thought and knowledge that ensued were widely recognized and were reflected in the papers presented at the conference.

Delegates were accommodated in St. John's College, so that after the formal sessions there was ample opportunity for further discussion and interchange of ideas. A jubilee dinner was held at the college, at which the guest of honour was Y. T. M. Tunku Ya'acob, the High Commissioner for Malaysia in the United Kingdom. The conference also provided the opportunity of paying tribute to Sir Eric Rideal for his long and valued service to the Association. The chairman read a letter from the Minister of Commerce and Industry, Federation of Malaysia, conveying deep appreciation of the service which Sir Eric had rendered, and presented to him an inscribed silver salver and a specially bound copy of NRPRA's new publication, *The Chemistry and Physics of Rubber-like Substances.*

NEWS and VIEWS

The John Fritz Medal, 1965 : Dr. F. R. Kappel

Dr. Frederick R. Kappel, chairman of the board of the American Telephone and Telegraph Company, has been awarded the 1965 John Fritz Medal, one of the highest honours to be bestowed by the American engineering profession. The award was announced by the United Engineering Trustees, Inc., custodian of the award, which is presented not more than once annually for "scientific or industrial achievement in any field of pure or applied science" by a special board appointed from the membership of five professional engineering societies. Dr. Kappel was born in Minnesota in 1902. He has had an outstanding career as an industrialist since he graduated in the University of Minnesota in 1924 as an electrical engineer with a B.S.E. degree. He began his career with the Northwestern Bell Telephone Company in Minnesota and joined the American Telephone and Telegraph Company in 1949; he was elected chairman of the board of directors in 1961. Dr. Kappel also serves as a director of the Chase Manhattan Bank in New York, and on many public bodies. He has honorary doctors' degrees from Lehigh University, Knox College, Union College, Ohio Wesleyan University, Rensselaer Polytechnic Institute, Columbia University, Williams College, the University of New Hampshire, and Michigan State University. The John Fritz Medal was established in 1902 by professional associates and friends of the noted industrialist and engineer. Among the previous holders have been Lord Kelvin, Alexander Graham Bell, Thomas A. Edison, Orville Wright, Charles F. Kettering, Vannevar Bush, Herbert Hoover, George Westinghouse, Guglielmo Marconi, and Benjamin Fairless.

Horticulture at Wye College: Prof. H. W. Miles

Prof. H. W. Miles, who will be retiring from the chair of horticulture at Wye College (University of London) at the end of the academic year 1964–65, graduated at the University of Bristol in 1923 and obtained his Master's degree in 1925. After a short period as biologist at the Kirton Agricultural Institute, he was appointed adviser and lecturer in agricultural entomology in the Zoology Department at the University of Manchester. There he made a special investigation of the sawflies of importance in Britain and was awarded a Ph.D. He obtained a D.Sc.(Manchester) in 1936. Then followed a series of investigations into the losses caused by wireworms to market-garden crops in Lancashire and Cheshire and the initiation of some of the techniques for the assessment of soil insect populations in relation to crop injury that were to prove of great value to the official advisory services from 1939 onwards. In 1942 Dr. Miles transferred to the Bristol province as advisory entomologist centred on the Long Ashton Research Station. When the National Agricultural Advisory Service was established in 1946 he was promoted to deputy provincial director in the West Midland Province, the post he was holding when appointed to the chair of horticulture at Wye College in 1947. At Wye his policy has been to ensure that equal attention should be paid to the three main sections of horticulture (fruit culture, market gardening and decorative gardening) and, with the full support of colleagues, he has secured the steady improvement in the science content of the degree course. Under Prof. Miles's guidance, the Department has developed research into fruit tree nutrition and orchard sward management, the problems of vegetable seed crop production and, latterly, the use of intermittent mist and supplementary lighting in the propagation of difficult ornamental plants. Post-graduate workers who have taken part in these investigations have now progressed to positions of responsibility in research stations at home and overseas. The demand for horticultural graduates of high calibre is likely to continue and Dr. Schwabe, who succeeds Prof. Miles, may well be called on to extend and diversify the Department's research facilities still more to meet this need.

Dr. W. Schwabe

Dr. W. Schwabe, who has been appointed to succeed Prof. H. W. Miles as professor of horticulture at Wye College (University of London), was born in 1920. He took first-class honours at Imperial College, London, in 1945, and then joined the research staff of the Institute of Plant Physiology at that College under the directorship of the late Prof. F. G. Gregory. Working on the mineral nutrition of plants in the group stationed at Rothamsted, and headed by Dr. F. J. Richards, he was awarded a Ph.D. in 1949. Later, his research was centred mainly on the physiology of flowering and the analysis of growth and morphogenesis in plants, and included a period of work at the Arctic research station of the Swedish Royal Academy. These researches have elucidated the action of environmental factors controlling flowering in the chrysanthemum and other plants, and have also revealed the dual control of flowering by internal inhibition and promotion. For these investigations he designed a new type of plant growth cabinet with natural illumination which has since been used extensively in other phytotrons. For this work Dr. Schwabe was awarded the D.Sc. degree in 1957 and the Huxley Medal of Imperial College in 1958. On the dissolution of the Institute of Plant Physiology at Imperial College he remained with Dr. Richards's research group, which was later transferred to Wye College as the Agricultural Research Council Unit of Plant Morphogenesis and Nutrition.

New Research Building for Pfizer, Ltd.

PFIZER, LTD., is increasing its research facilities at Sandwich, Kent. The new building, costing £370,000, is planned to be completed by the end of next year, but this is only the first stage of a three-stage programme which when completed will house most of the pharmaceutical research departments. This will enable the research work being conducted in various locations at Sandwich to be centralized and, at the same time, allow the Group to move into new areas of research such as tropical medicine. The major fields in which the group is already heavily engaged and which will be given even greater emphasis are those of the cardio-vascular diseases and virology. The first stage, of 30,000 ft.^{2}, will house the chemical and clinical research departments plus a lecture theatre with a seating capacity of 75, a library and research headquarters. The library, on the ground floor, will contain a fire-proof vault for storing research data and other irreplaceable documents. Four chemical research laboratories will be situated on the first story together with the research headquarters and micro-analytical and chromatography laboratories, and space for nuclear magnetic resonance investigations. On the second story will be six chemical research laboratories, a conference room, wash-up area and workshop. Special features will be a 'safe' laboratory where overnight and long-term experiments can be conducted in isolation and a large-scale laboratory for producing intermediates and compounds required in more than normal bench quantities. On the roof will be hydrogenation and isotope laboratories. The isotope laboratory will be used for 'tagging' certain new therapeutic compounds with radio isotopes so that their activity in the body can be accurately measured.

Representational Services Overseas

IN opening a debate in the House of Commons on July 29 on the Plowden Report on *Representational Services Overseas* (*Nature*, 202, 1039; 1964), Mr. H. Berkeley challenged the retention of the Commonwealth Relations Office and the Foreign Office as separate Ministries and argued cogently for a Department of External Affairs, covering both Commonwealth and non-Commonwealth countries, with a ministerial structure based on geographical areas. He also suggested a Cabinet Minister for Overseas Development, with much wider responsibilities than the Secretary for Technical Co-operation. Mr. C. P. Mayhew, who followed, questioned the wisdom of any such fusion and was inclined to support the recommendation of the Plowden Committee, and in this he was also supported by Sir Charles Mott-Radclyffe. The Under-Secretary of State for Commonwealth Relations and for the Colonies, Mr. N. Fisher, who replied on the debate, admitted that there might be disadvantages in having two departments, but thought that these disadvantages were exaggerated and that the balance of argument in practice was in favour of two departments. He did not deal with the point about development aid and the Department of Technical Co-operation, but discussed the question of recruitment at some length, particularly with regard to widening the basis of recruitment. He agreed that it was important to encourage university graduates to compete for entry into the executive branch as well as the administrative branch, but was silent as to the desirability of a larger recruitment of those with a scientific background urged by Mr. Mayhew. No speaker referred to the point at issue between the Estimates Committee and the Plowden Committee on the margin of staffing the Service (see *Nature*, 203, 797; 1964).

Industrial Training Boards

IN a short debate on the industrial training boards in the House of Commons on July 22, opened by Mr. R. E. Prentice, the Minister of Labour, Mr. J. B. Godber, said that the first four training boards established under the Act, for the construction, the wool, the engineering and the iron and steel industries, had all met at least once. In the light of the advice of the Central Training Council, he had selected shipbuilding, cotton, construction materials and public utilities (gas, water and electricity) as the next four industries for which training boards should be established. At its meeting on July 23, the Central Training Council would consider its own committee structure, with the view of dealing effectively with its varied tasks on a regional and functional basis. The Ministry now had two branches, each under an Assistant Secretary, dealing with the implementation of the Act: one was concerned with preparations for establishing further boards, and the other with relations with those already established. There was also at present a technical staff, under the chief technical adviser, with two assistant technical advisers, to advise on technical aspects of training; a deputy was shortly to be appointed. Grants of up to £10,000 had been made to assist the boards until they could raise their own funds from a levy, and they were also being assisted in compiling a register of firms in each industry. The Construction Board and the Wool Industry Board each had a deputy chairman, as well as a chairman, but the other two boards, which had chairmen from within the industries concerned, had not.

Public Libraries and Museums

IN moving the second reading of the Public Libraries and Museums Bill in the House of Lords on June 30, the Minister of State for Education and Science, Lord Newton, explained that museums and art galleries had recently been surveyed by the Standing Commission under the chairmanship of Lord Rosse, and when the Bill was introduced into the House of Commons in February it was the Government's intention to make no substantial change until the Survey had been further studied. It had been represented, however, that certain changes would command a wide measure of support and should be made without waiting for further legislation on museums. It also appeared that the existing law regarding charges for admission to museums and art galleries was full of anomalies and could not be re-enacted. For these two reasons, Clauses 12–15 dealing with museums and art galleries had been extensively revised.

Under the revised Clause 12 all library authorities would continue to have powers to provide and maintain museums, and any other authority which now maintained a museum would be able to do so. In addition, any local authority would be able to provide a museum or art gallery if it obtained the consent of the Secretary of State. The amended Clause 13 removes the original prohibition on charges for admission, but requires local authorities to take into account the need to ensure that the museum or gallery plays its full part in promoting education in the area, and to have particular regard to the interests of children and students. Lord Newton added that it was not the Government's intention to encourage local authorities to impose charges. Clause 14 allowed library authorities or authorities maintaining a museum or art gallery to contribute to the expenses incurred by any person, either in providing or maintaining a museum or art gallery, or in providing advisory or other services, or financial assistance, for it. The second power had been inserted with the needs of regional museum organizations particularly in mind. Clause 15 gave effect to the recommendation of the Standing Commission that the power taken by some authorities under private Acts to establish a fund for the purchase of exhibits should be made general.

Apart from some discussion of the clause relating to admission charges which, as Lord Newton anticipated, was not regarded as entirely satisfactory, the debate centred mainly on three points. First, on finance: Earl Attlee argued that there was need for some kind of Government grant to the large regional centres which served wide areas, although it was accepted that it would be easier to wait for the present review of central and local Government finance to be completed before changing the finance of the library service. The need for some immediate contribution from the central Government was urged by Viscount Eccles and by Lord Shackleton, who challenged in particular the Government's treatment of the National Central Library, for which he urged further consideration and support. Secondly, the question of the needs of students was urged by Earl Attlee as well as other speakers, and the importance of every library having a chief librarian and fully qualified staff with adequate remuneration and status was repeatedly emphasized. Thirdly, Viscount Eccles and others emphasized the importance of adequate research, and Lord Newton, in replying on the debate, said that under Clause 1 the Secretary of State would be able to commission research and also to draw on the services of the Architects and Buildings branch of his Department, both for research and for development work on public library buildings. He assured the House that this question would be considered when the Act came into operation. Earlier he had estimated that the improvement of standards of service might involve an increase of perhaps 50 per cent in the present cost of about £23 million, though this increase would be spread over several years.

South African Museum

The annual report of the South African Museum for the year ended March 31, 1963, breaks with a 105-year-old tradition and provides, in an attractive format, a general account of the present main activities and future plans (Pp. v+23. Capetown: South African Museum, 1964). This replaces a record of accession data, donors, etc., which in future will be prepared but not printed. The policy of the Museum is to maintain a balance between funds allocated for research and educational activities. In the year under review, 25 major field trips were undertaken in addition to numerous short ones. Major extensions to the buildings are in hand and the new library and administrative block has been completed. A new exhibition of South African birds, a diorama to show bird life at Rondevlei and a display of Cape birds have been prepared. During the next two or three years it has been decided to concentrate on research in marine biology, palæontology and entomology by teams of workers on the staff.

Transvaal Museum, Pretoria

As usual, this Museum's report is printed in English and Afrikaans (Transvaal Museum. Report for the year ending March 31, 1963. Pp. 31. Pretoria: Transvaal Museum, 1964). The study collections, which form the basic material for research, continued to be augmented through selective collecting by members of the staff, and by donations. Further accommodation is urgently needed for the storage of these collections. A number of short collecting and survey trips have been undertaken to areas of particular scientific interest. Five new large mammal habitat cases have been installed. In the Cultural History section an interesting exhibition, "Old Cape Silver and Furniture", has been arranged.

Science in the Less-well-known Languages

In the April (1964) issue of *Science East to West*, Mr. J. Garrido, deputy director of the Documentation Centre of the National Centre for Scientific Research, Paris, contributes an article on scientific and technical publications in the lesser-known languages. His analysis of articles published in 1962 indicates that English (66 per cent), Russian (13 per cent), French (11 per cent) and German (8 per cent) account for all but 2 per cent of published work in nuclear physics. In applied chemistry, the agricultural sciences and geology, other languages account for 14–18 per cent, the proportion varying slightly in the different subjects. Among these other languages, Japanese and Italian come first, each with about 20 per cent of the total in languages other than English, Russian, French and German. Polish, Romanian, Czech, Spanish and Ukrainian come next with 10–5 per cent, followed by Hungarian, Serbo-Croat, Bulgarian, Dutch, Swedish and Portuguese with 5–1 per cent. The most surprising result is the place of Chinese, which in M. Garrido's figures only stands first among 30 languages with less than 1 per cent of the output of the scientific literature in languages other than English, Russian, French and German. In applied chemistry, the proportion in English is 39 per cent, in the agricultural sciences 42 per cent, and in geology 33 per cent; for German the corresponding percentages are 20, 11 and 8 respectively; for Russian, 17, 19 and 35; and for French, 8, 10 and 10.

New Approach to National Health Service

One in ten of the adult population is probably suffering from a potentially serious illness which is unknown to his or her doctor. Not all these need medical attention; but many do, and delay in starting treatment is frequently responsible for unnecessary deaths and disablement. 2,500 deaths from cancer of the cervix and about 4,000 cases of blindness from cataract and glaucoma each year might be prevented if treatment had been started sooner. These facts are brought out in a report issued by the Office of Health Economics entitled *New Frontiers in Health: a Review of the Incidence, Impact and Implications of Minor and Unrecognized Illness in the Community* (Pp. 32. London: Office of Health Economics, 1964. 2*s*.). The report criticizes former delays in introducing measures which could demonstrably improve the health of the nation. During the 1930's about 20,000 child deaths from diphtheria could have been prevented had Britain started an immunization campaign at the same time as the Canadians. "It seems clear", says the report, "that powerful advocacy is sometimes required before even the most obvious advances in the health field are put into practice". It also directs attention to the amount of minor ill-health which is untreated. For every person who visits a doctor, there are probably three more who suffer from a minor illness without consulting him. It is estimated that minor illnesses cause the loss of about 25 million working days each year. Much of it is among women, for whom short sicknesses cause about two and a half days' absence a year. For men, short sicknesses on average are responsible for less than one day off work each year. The report concludes: "It is unrealistic to expect that everyone should enjoy 'perfect' health, and it would be unreasonable to strive for it. Man will always be faced with more or less important diseases and disorders caused by the environment in which he exists, and which, to a large extent, he has created. On the other hand, there is very much that could be done to correct disorders, to control diseases, and to raise the present general level of health. The costs which this would involve should be seen in perspective against the benefits in having as healthy a community as possible".

Bausch and Lomb Metallographs

The 'Dynazoom' series of metallographs recently introduced by Bausch and Lomb consists of a versatile set of bench-type models suitable for general metallurgical work both in industry and in schools and colleges. The instrument is based on the inverted microscope principle and there are models for both visual and photographic work, using bright field, dark field or polarized light illumination. The exclusive 'Dynazoom' system permits extended continuous magnification ranging from ×25 to ×800, at a twist of a dial. With accessory optical components the range can be extended to ×3,750. The optical elements are enclosed in a 'Power Pod' housing for protection against dirt and dust. The housing can be removed from the main body of the instrument and a different 'Pod' (monocular or binocular) substituted. The 'Power Pod' bodies are inclined, providing a comfortable viewing angle for prolonged examination and can be rotated through a full 360°. A unique feature of the metallograph is a built-in rotating reticle turret with six apertures to accommodate a variety of measuring reticles which can be quickly and easily inserted or removed through a door in the bottom of the instrument. Photomicrography is a simple procedure. The photobinocular zoom body can be obtained separately and is directly interchangeable with any other zoom body. Four cameras are at present available: 35 mm, $2\frac{1}{4}$ in. × $3\frac{1}{4}$ in. 'Polaroid', and the Bausch and Lomb '*L*' and '*N*' models. A green filter with a peak at 500 mμ is standard on all instruments. There are provisions for both black-and-white and colour reproduction of metallic structure, and colour-compensating, colour-balancing and neutral-density filters are also available.

Lalor Foundation Grants for 1965

The Lalor Foundation has announced the programme of awards for 1965, which it is offering for support of research on the fundamental biochemical and physiological mechanisms concerned with fertility and the early stages of reproduction in various forms of life. The objectives are to further the knowledge and understanding of the basic phenomena involved and to extend and develop the possibilities for effective regulation and control. The awards are open to all nationalities, and may range up to 8,000 dollars a year, depending on the scope and duration of the projects approved. Preference will be given to younger members of university and college faculties and staff, with an upper age-limit of forty-one years. The work may be carried on at the applicant's own institution or elsewhere. The Foundation will also grant post-doctorate summer or short-term research awards at the Marine Biological Laboratory at Woods Hole, Mass., or elsewhere for appropriate projects in the fields specified. These awards will normally not exceed 1,150 dollars for a single man or a woman, 1,350 dollars for a married man working at his home institution, and 1,500 dollars for a married man with principal programme at another institution. Further information and application forms can be obtained from the Lalor Foundation, 4400 Lancaster Pike, Wilkington, Delaware, 19805. The final date for receipt of executed application forms, complete with supporting data, is January 15, 1965. Notification of appointment will be on or before March 15.

North of England Soils Discussion Group

A discussion group is being formed covering broadly the North of England to further the investigation of all aspects of the soil. Membership is invited from individuals or educational and vocational bodies that have an interest in the soil. It is intended to embrace all aspects of the investigation of the soil, including the biological, cultural, physical and economic, as well as the purely pedalogical, and its bearing on land use. An annual meeting will be held, to include a field excursion, and a paper-reading session with discussion, probably in September. A specific topic will be the main feature of each meeting, and will largely determine the locality to be visited. Further information concerning membership and meetings can be obtained from: Dr. V. B. Proudfoot, Department of Geography, University of Durham; Mr. G. D. Ashley, Soil Survey of England and Wales, Kenton Bar, Newcastle upon Tyne; Mr. P. J. A. Howard, Nature Conservancy, Grange-over-Sands, Lancashire; or from the secretary, Mr. H. T. Davies, Soil Chemistry Department, National Agricultural Advisory Service, Government Buildings, Lawnswood, Leeds, 16.

The first meeting of the North of England Soils Discussion Group on "Soils and Land Use Problems in the Marginal Farming Areas of the Pennine Foothills" will be held in Lancashire during September 28–30. Further information can be obtained from Mr. H. T. Davies.

Announcements

The President's Lecture of the Institution of Electronics, entitled "The Vanishing Electron", will be delivered by Dr. R. C. Jennison at the Manchester College of Science and Technology on October 3. Further information and tickets can be obtained from the General Secretary, Institution of Electronics, 78 Shaw Road, Rochdale, Lancs.

The fourth annual meeting of the American Society for Cell Biology will be held in Cleveland, Ohio, during November 11–13. The programme will include a symposium on "The Structure, Function and Origin of Biological Membranes". Further information can be obtained from Dr. D. Green, Institute for Enzyme Research, 1,170 University Avenue, Madison 6, Wisconsin.

A symposium on "Models for the Perception of Speech and Visual Form", sponsored by the Data Sciences Laboratory of the Air Force Cambridge Research Laboratory, will be held in Boston during November 11–14. Further information can be obtained from Mr. G. A. Cushman, Wentworth Institute, 550 Huntington Avenue, Boston, Massachusetts 02115.

A symposium on "The Use of Radioisotopes in Animal Nutrition and Physiology", sponsored by the International Atomic Energy Agency and the Food and Agriculture Organization, will be held in Prague during November 23–27. Topics under discussion will include: physiology and biochemistry of milk secretion; metabolism and requirement of trace elements including magnesium; the influence of environmental factors on animal production and reproduction. Further information can be obtained from IAEA/FAO Symposium Secretariat, Kärntnerring 11, Vienna I.

A short course on "Solution Properties of Polymers", arranged by the Department of Chemical Technology of the Bradford Institute of Technology, will be held in the Institute during November 13–14. The course, which is intended primarily for graduates, will include lectures on: viscosities of dilute solutions; fractionation; determination of molecular weight distribution; solution properties in relation to polymer properties; newer methods of molecular weight determination. Further information and forms of application can be obtained from the Registrar, Bradford Institute of Technology, Bradford 7.

THE U.K. ATOMIC ENERGY AUTHORITY

THE tenth annual report of the Atomic Energy Authority* covers the year ended March 31, 1964, in which the Authority's staff was reduced by about 5 per cent because production of uranium-235 for military purposes at Capenhurst ceased and most of the capital works programme has been completed. Of the £45 million expended on civil research and development, £36 million was current expenditure and £9 million on capital facilities; research, development and design contracts with industry, universities, etc., amounted to £4,612,000 compared with an estimated £4,223,000 in 1964–65; contributions towards International Atomic Energy Agency projects were £2·48 million and grants to the National Institute for Research in Nuclear Science £8,998,000, compared with an estimated £1·36 million and £9,648,000, respectively, in 1964–65. Of 2,830 engineers and scientists employed at March 31, 1964, 180 were doing work for other organizations on repayment, 1,900 were engaged on the reactor development programme and reactor systems research, on which current expenditure is estimated at £26 million, 470 on general research (£6 million), 200 on plasma physics and fusion research (£3 million), and 80 on isotopes research (£1 million). Attention is directed to a reduction in the balance sheet of £50 million in the value of work in progress, which is due mainly to the transfer of nearly £30 million to "loss on revaluation of fissile material", representing a writing-down of the value of material held for research purposes to bring the valuation in line with world prices. Uranium ore, no longer required for military purposes, other than supplies purchased for the nuclear power programme, will form a national stockpile in the custody of the Authority as agent for the Secretary of State for Education and Science, and the cost of the uranium in this stockpile will in future be excluded from the Authority's balance sheet. Of the £52·5 million received from the Authority's trading and other commercial activities during the year, £39·5 million was from sale of reactor fuel, fuel services, etc., £7·9 million from sales of electricity, £1·6 million from sales of isotopes and £2·7 million from sales of reactor-grade graphite.

On the production side development work on the gas centrifuge as an alternative to gaseous diffusion continued satisfactorily and productivity in the magnox fuel manufacturing process continued to increase, while the anticipated peak in production of magnox fuel at Springfields was reached. A separate chapter devoted to the reactor development programme estimates that at March 31, 1964, 19 per cent of the scientists and engineers in the Reactor Research and Weapons Group were engaged in work on the advanced gas reactor, 17 per cent on the steam-generating heavy-water reactor system, which has the advantage of lower enrichment than the advanced gas reactor and the potentiality of producing superheated steam, 38 per cent on the fast reactor, 14 per cent on the civil marine reactor and 12 per cent on the high-temperature gas-cooled reactor for the *Dragon* project at Winfrith. In the advanced gas reactor encouraging progress is reported in protecting the graphite moderator from corrosion by the carbon dioxide coolant under irradiation and much information was also obtained on the dimensional changes in graphite caused by irradiation from irradiation experiments. The operational availability of the Windscale advanced gas reactor during its first year of power operation was 87 per cent and compares favourably with any other nuclear reactor built solely as a nuclear power station or otherwise. With fast reactors the outstanding achievement was to get the Dounreay fast reactor operating at full power and to continue at full power for the maximum time to build up irradiation experience of fast reactor fuels. General predictions of the kinetics of a high-power fast reactor have been shown to be substantially accurate and steps taken in design of the core to eliminate a positive power coefficient were successful. On marine reactors little is added to what was said in the Padmore Report (*Nature*, 202, 1248; 1964); work on the integral boiling reactor was mainly confined to physics of burnable poison cores and to fuel element and core design investigations; work also continued on burnable poison cores and experimental physics studies were made of the characteristics of regular fuel element clusters, as well as investigations of the use of plutonium as a nuclear fuel for marine reactors.

A further chapter dealing with research on reactor systems records that, in the programme of nuclear measurements to provide data for calculating the physics characteristics of proposed reactors, the emphasis continues to be on measurements for fast reactors. A general investigation continued into the mechanism by which neutrons transfer their energy to liquids and solids and are thus brought into equilibrium with the atoms of a moderator, and a major advance in the established technique of transfer-function analysis for measuring the dynamic response of a nuclear power plant has been linked with the development of a neutron generating tube of high output capable of being modulated at frequencies up to 1,000 c/s. Work on fuels has included studies of solid solutions of plutonium dioxide in uranium dioxide to determine the chemical (phase) stability under various conditions, and in work on carbide fuels reactor-grade material has been obtained by heating granules of fissile oxides with carbon in a stream of argon. Other work has been concerned with canning and structural materials, moderators and coolants and the design of biological shields for power reactors.

Among examples selected to illustrate the Authority's programme of general research in this report may be mentioned work which is directed at devising mathematical methods by which computers can be used more efficiently and applied to a wider range of problems. In a programme of basic research on solid-state physics the emphasis is now moving to non-metallic solids such as oxides and carbides. The fundamental causes of changes in solids induced by radiation are also being investigated, while basic information bearing on steam-cooled systems is being sought in studies of the radiolysis of water-vapour, in which first results indicate that the net radiolytic decomposition of pure water is negligible, but with vapour containing ammonia or oxygen the primary decomposition is comparable with that of pure water. Other long-term research is concerned with the physical and chemical properties, and the fabrication behaviour, of the oxides, carbides, nitrides, sulphides and phosphides of fissile and fertile elements, especially the carbides. Some work also continues on fissile metals, and protactinium oxide has been investigated in detail for comparison with the oxide systems of the other actinide elements from thorium to plutonium. A major effort is devoted to improving existing methods of analysis and applying new ones, while an increase in the resolution with which chemists can measure the energies of α-particles has led to a tenfold improvement in the sensitivity of certain measurements in health physics. The utility of γ-ray spectra for identifying the radionuclides present in various materials has been increased by the development of an automatic method of analysing complicated spectra and an absolute hygrometer has been developed for measuring the humidity of the stratosphere in investigations on fall-out.

* United Kingdom Atomic Energy Authority. Tenth Annual Report for the period 1st April, 1963–31st March, 1964. Pp. ix + 89 + 8 plates. (London: H.M.S.O., 1964.) 6s. 6*d*. net.

In plasma physics and fusion research the main problems are still to identify, understand and control the many instabilities which prevent magnetic fields from confining extremely hot ions and electrons for more than a relatively brief moment. While these instabilities remain as a potential source of trouble in closed systems, there are now indications that they can be overcome in the open-ended magnetic traps. The programme also includes two experiments in 'Minimum *B*' geometry designed to see if the same freedom from interchange instabilities noted by Ioffe at the Kurchatov Institute will apply at higher plasma densities and with different methods of plasma injection. Besides investigations with a cusped field trap and a theatron trap, containment with closed lines of force has been investigated and basic investigations made on plasma itself, particularly the propagation characteristics of the wide variety of wave motions which a magnetized plasma can support, and also the processes which can arise from collision between its constituent particles. At the Wantage Research Laboratory the feasibility of radioisotope X-ray fluorescence analysis for on-stream assay of zinc–lead ores has been investigated in co-operation with the Department of Scientific and Industrial Research, while investigations bearing on health and safety have led to the development and manufacture of a personal neutron dosimeter. Studies of radioactivity in the human body continued using whole-body monitors and bioassay methods to determine the metabolic behaviour of nuclides, and continued physico-chemical study of chelating agents confirmed that diethylenetriamine pentacetic acid and triethylenetetramine hexacetic acid assist the removal of plutonium from the human body, but more effective and less toxic compounds are being sought.

The Reactor School programme at the Postgraduate Education Centre set up at Harwell on April 1, 1963, has been revised, and, after transfer of four of the more elementary courses, three new courses have been added: physics for engineers; language and technical writing; and a refresher course for senior technical executives. In collaboration with the European Nuclear Energy Agency a one-week residential course was given on health and safety aspects of radiation in industry for Trade Union officials. Of 379 students attending these courses, 340 were British and 39 from overseas, while 490 students attended a new series of postgraduate courses, and another 300 the 14 courses held in the Isotope School.

While the non-industrial staff fell over the year from 20,008 to 18,864 and industrial employees from 18,350 to 17,098, the Authority made it clear to their staff that there is a large and continuing volume of work for the Authority, including civil research and development as well as production and processing. Some recruitment continued and the level will be raised in 1964, the need for young scientific and engineering graduates for research, design and development, and for training as future managers being mentioned, while 202 apprentices were recruited compared with 230 in the previous year.

The Authority has also published the tenth anniversary issue of *Atom*† including both an illustrated summary of the tenth annual report and an illustrated review of the developments during 1954–64.

THE SOUTH AFRICAN ATOMIC ENERGY BOARD

THE South African Atomic Energy Board was set up in March 1949, and at first confined its operations almost exclusively to administrative procedures related to the mining, extraction and sale of uranium concentrates, the distribution and control of radioisotopes, mineral investigations, and the study of the production of heavy water. During 1957 detailed planning of an atomic energy research and development programme for South Africa was started, and on September 5, 1959, the then Minister of Mines, Mr. J. de Klerk, announced the Government's acceptance of the proposed programme. This covered an initial period of five years. *The Way to Pelindaba* is an illustrated description of the main activities during that period 1959–64*.

The programme called for both electric power production by nuclear fission, and for radioisotope and radiation applications, and necessitated the provision of a nuclear reactor for research and a suitably located research centre. It was decided, in 1960, to construct a 20-MW high-flux light water moderated and cooled reactor of the Oak Ridge type, suitable for materials testing and for operation initially at about 5 MW. A contract for the supply of *SAFARI*-1 (*S*outh *A*frican *F*undamental *A*tomic *R*eactor *I*nstallation) was signed with the authorities of the United States. A site, on a farm formerly known as Wilgegund, was chosen for the nuclear research centre, and named Pelindaba, from the Bantu *pelila indaba*, meaning 'the discussions are finished'. Construction commenced in July 1961, and two years later, in July 1963, the administration building and part of the reactor building were occupied. The chemistry building, the Van de Graaff accelerator building, the water purification works and a portion of the reactor engineering building were completed by the end of 1963. Unfortunately, accidental damage to the reactor vessel of *SAFARI* in the United States during test delayed its delivery to South Africa, but the repaired vessel eventually arrived on Christmas Day 1963 and by March 1964 it was installed, together with most of its heavy concrete shield, within the reactor building. The Van de Graaff accelerator—a 3-MeV high-intensity beam type—which provides a source of mono-energetic neutrons, with pulsing if required for the time-of-flight method, has also been erected and is now in commission. A detailed description of the site and layout of the nuclear research centre, together with diagrams of the site buildings, the accelerator and reactor, is given in the companion booklet *Pelindaba* (Brochure No. 2).

It is well known that South Africa contains some of the world's largest reserves of uranium and has been one of its largest producers. Indeed, until recently, 17 uranium extraction plants handling about 20 million tons of residue slimes from 26 mines, eight contact-process sulphuric acid plants, and a factory for the conversion of the custard-yellow cream emanating from the extraction plants were in continuous operation. All forms of refined uranium are produced in substantial quantities, the products including uranium metal, its carbide, trioxide and tetrafluoride, and small quantities of hexafluoride. A pilot plant has been constructed to investigate the production of a nuclear-grade uranium product, containing only a few parts per million of impurity, from the uranium extraction plants at the gold mines at Bufflesfontein. This is known as the Bufflex Project and was started in October 1963.

The research staff of the Atomic Energy Board, some eighty of whom have been trained or are still training at nuclear research establishments in some ten countries outside Africa, belong to eight divisions. The Geology Division, though of primary importance, is small, because many of its activities are covered by the Geological Survey Office of the Government. The Extraction Metallurgy Division, which is housed at the Government Metallurgical Laboratory, makes use of the services provided there. The third division which relies on external facilities is the Life Sciences Division, and the number of its staff at Pelindaba is accordingly limited. The remaining five Divisions—Reactor Engineering, Chemistry, Physics, Physical Metallurgy, and Isotopes and Radiation (Protection and Application)—comprise the bulk of the research staff stationed at or attached to the National Nuclear Research Centre at Pelindaba, and at present three laboratory blocks are at their disposal. There are in addition three technical divisions. The Research Reactor Division will operate the reactor *SAFARI* for the research scientists; the Technical Services Division undertakes the provision of services such as power, water, compressed air and workshop facilities; and the Liaison and Information Division is responsible for external relations and the provision of information to the staff and outside bodies.

---

* South African Atomic Energy Board. Brochure No. 1: *The Way to Pelindaba.* Pp. 28. Brochure No. 2: *Pelindaba—National Nuclear Research Centre of the South African Atomic Energy Board.* Pp. 31. (Pretoria: South African Atomic Energy Board, 1964.)

The final section of the report deals with future activities. In the late 1970's the world demand for uranium may exceed its availability and consideration may have to be given to low-grade sources of uranium. Rapid developments in enriched uranium reactors have directed attention to enrichment processes in which uranium hexafluoride is of importance, and the production of this particular compound is being investigated, together with that of zirconium, hafnium, thorium and the rare earths. The recovery of beryllium, niobium, tantalum and lithium from deposits of pegmatites is also being investigated. The power reactor project is to be pushed ahead and this will require the evaluation and testing of fuel, materials and components, together with the development of fabrication techniques. Solid-state investigations of irradiation effects and neutron diffraction investigations will be needed, and in order that this work may proceed before the neutron flux from *SAFARI* becomes available, a large γ-radiation source will be installed. The Van de Graaff building is to be extended to accommodate the whole of the expanded Physics Division, and a new library building is to be provided to relieve congestion in the administration building. For the second five-year programme to reach the target figure of expenditure of *R*.3 million per year the Government has trebled its contribution and the Electricity Supply Company its share five-fold. Heavy industry, too, has pledged an amount totalling more than twice its contribution during 1959–64.

S. WEINTROUB

PRESERVATION OF RURAL ENGLAND

THE dominant impression left by the thirty-eighth annual report of the Council for the Preservation of Rural England for the year 1963–64 * is the magnitude of the scope there still is for such independent voluntary effort, and the vigilance and vision, as well as the balance and fairmindedness, with which the Council, through its Executive Committee, diligently strives to ensure that harmful development is never allowed without question. Wherever possible, the needs of the countryside as a whole are balanced against what are often private or temporary ends. While the year has brought some evidence of increasing official awareness of the need to look well ahead in planning matters, and in estimating future demands on land and natural resources, the report notes that amendment of the National Parks Act, 1949, is still long overdue, the findings of the Royal Commission on Common Land in 1958 have still to be implemented, and the coast is still subject to piecemeal development and divided control. The circular issued to local authorities by the Ministry of Housing and Local Government in September 1963 emphasized the need for positive planning of coastal areas. It is welcomed, but it is regarded as being too local in scope. What is needed is a national policy for the preservation of the countryside based on a Land Budget, allotting land used according to definite patterns of priority.

The Council is sympathetic to the difficulties of the Central Electricity Generating Board and recognizes that sites for power stations are hard to find, and that there is still a formidable gap between the cost of overhead and underground transmission. The generation, transmission and distribution of electricity present the Council and the planning authorities with difficult problems, and the concern expressed in this report, especially with regard to overhead lines, will not be diminished by the subsequent decision of the Minister of Power to disregard the recommendations of his own inspectors and the objections of all the local authorities concerned and allow the Central Electricity Generating Board to run a supergrid power line in 160-ft. pylons over the Sussex Downs. The timing of the announcement to coincide with the parliamentary recess may well have justified the Council in thinking that the scales are weighted against amenity and that there is substance in Lord Chorley's suggestion that the replacement of the Ministry of Town and Country Planning by one of Housing and Local Government represents more than a change of name and results in a situation in which decisions against amenity are taken by one who judges his own cause. On water undertakings the Council is convinced that traditional sources of water are likely to prove inadequate before long and that a national water grid will be needed. Major reliance will eventually be placed on the distillation of sea-water and the re-use of water. It points out that the Minister of Housing and Local Government himself agrees that the Conference on Water Supplies in the north-west dismissed the distillation of sea-water too lightly.

The Council has made constructive proposals concerning many road projects. It welcomes the Buchanan Report and the South-East Study, as well as the proposals put forward towards the end of 1963 by the Standing Conference on London Regional Planning under the title *Population, Employment and Transport in the London Region: Meeting the Situation*, but the report stresses the need for research into every aspect of life in towns, of movement between towns, and of their relations with one another. This involves the consideration of regional groupings and, beyond these, of national problems. Concern is expressed at the shortage of qualified planning staff, and the Council is profoundly disturbed as to the future of the 'Green Belts', on which it finds the Minister's attitude disturbing, in spite of an explicit statement that the Government has no intention of abandoning the Green Belt policy.

Inevitably, much of the report is concerned with comments on particular topics, but the broad subjects covered—including rural housing, litter and refuse disposal, commons and open spaces, nature conservation, trees, national parks, preservation of buildings, the siting of radio and television stations, caravan and camping sites, oil pollution of the sea, mineral undertakings—illustrate its wider range of interests and the many spheres in which it has been called on for advice or action.

MODERN GLASS TECHNOLOGY

BOTTLES of skin, gourd or calabash (tree or climbing plant, the fruit-shell of which has been emptied and dried), alabaster, ivory and even beaten gold, have been in use down the centuries, things both of beauty and utility; many relics are with us to-day, in museums and elsewhere, all over the world. But for several millennia the most favoured bottle material has been ordinary glass, starting with the craftsman glass-blower (still with us in many specialized pursuits, particularly concerning apparatus for scientific laboratories), graduating by moulding processes ultimately to the fully automatic bottle-making machines operating to-day. It may not be generally realized that glass as such is unique matter. It is not a true solid, but, according to C. L. Boltz in an interesting article in *Catalyst*, Vol. 12 (Industrial Journal of Shell Chemical Co., Ltd., London, Spring 1964), " . . . scientifically . . . a super-cooled solution that still flows over a long period of time . . . it is not crystalline in the sense that atoms are arranged in regular geometrical patterns . . . it is mainly amorphous, shapeless, and shatters randomly when it is abruptly broken".

In the early days glass products were usually coloured green, amber, blue or ruby, due to impurities such as iron, manganese, etc. It was not until 1908 that the first colourless glass bottles were produced in London. "The first university department in the world for the scientific investigation of glass technology was formed at Sheffield under Prof. W. E. S. Turner and has achieved international recognition. The use of polarized light for the detection of stress-lines in bottles and the importance of the glass surface in the retaining of strength are just two of the developments that have led to to-day's industrial glass technology." Apart from Sheffield, glass technology is now also the concern of the British Glass Industry Research Association (formed as recently as 1955) and the Glass Manufacturers' Federation.

Such has been the phenomenal advance in research and manufacturing techniques in recent years that it is estimated that, in Britain alone, some 4,500 million glass containers are manufactured per annum. Collaterally there has been the challenge of tin in replacing glass containers and more recently some of the thermoplastics, notably polyethylene. But in quite a different and perhaps more refined sphere of glass technology comes the highly skilled and expert precision operations of those firms concerned with manufacture of optical glass.

The word 'Jena' conjures up many memories, past and present, of lenses, microscopes and other optical instruments, and the bi-monthly *Jena Review* (VEB Carl Zeiss Jena, English translations available), now in its ninth year, makes available much technical information of present-day value to optical physicists and others concerned with precision optical equipment in this and allied fields. The issue No. 2, 1964, contains, *inter alia*, informative articles on synthetic crystals of fluorite and salt from melts, alum and quartz from solutions made in Jena; on objective photo-electronic testing or precision glass scales; preparation of fibre surfaces for electron microscopic examinations; spectrophotometry in the near infra-red with the '*UR* 10' Spectrophotometer, and linearity tests of other infra-red instruments. This review is an attractive publication and yet another example of a high-quality house journal.

KÁRMÁN VORTEX-STREETS IN EARTH'S ATMOSPHERE

By Dr. K. P. CHOPRA
Melpar Inc., Falls Church, Virginia
AND
L. F. HUBERT
U.S. Weather Bureau, Washington, D.C.

THE mechanism for the production of eddies on the planetary scale (cyclones) and those on the microscale (turbulent eddies) have been extensively investigated. The recent weather satellite results[1] have revealed the existence of the mesoscale eddies which are on an intermediate scale that is too small to be delineated by the standard weather observation network and are too large to be seen by an observer on the ground or even pictured from a high-flying aircraft. These eddies, shown in Fig. 1, are formed in the wakes of islands and have been observed to persist at downstream distances of a few hundred miles. They are made visible by patterns in the stratocumulus clouds lying beneath a strong inversion about 0·5–1 mile above the ocean surface. These eddies have a band-width of the order of the cross-stream diameter of the island, and bear a certain resemblance to the classical von Kármán vortex-street pattern shown in Fig. 2 and observed in the laboratory investigations of wakes behind obstacles to fluid flow. The purpose of this communication is to examine the properties of these eddies in the light of this apparent resemblance.

Viscosity plays two parts in the flow pattern of a Kármán vortex-street. First, it leads to the formation of the boundary layer in which vorticity is generated and the vortex-pairs are formed, the vortices being shed alternately near each edge of the obstacle. Secondly, the strength of the eddies is dissipated by the mechanism of diffusion; the size of an eddy increases and its strength decreases as it propagates downstream, until its region of influence overlaps that of a neighbouring eddy of opposite circulation. In all other respects, the fluid may be regarded as perfect (inviscid).

The rate N of shedding of the eddy pairs is given by:

$$N = u_e/\alpha \tag{1}$$

where

$$u_e = u_0 + (k/2\alpha)\tanh(\pi h/\alpha) \tag{2}$$

is the speed of propagation downstream of the eddies in a co-ordinate system fixed to the obstacle, u_0 is the speed of the undisturbed flow, α is the longitudinal spacing (pitch) between two eddies of similar circulation of strength k.

The drag per unit length on the obstacle, being equal to the rate at which momentum is transferred to the wake of the obstacle, is given by:

$$D = 2\rho h u_e\ (u_0 - u_e)\ \coth(\pi h/\alpha) \qquad (3)$$

where ρ is the density of the fluid, and h is the lateral spacing (band-width) between the two vortex-rows, approximately related[2] to d as:

$$C_D = D/\left(\frac{1}{2}\right)\rho d u_0^2 \approx h/d \approx 1{\cdot}25 \qquad (4)$$

for circular cylinders. Here C_D is the coefficient of drag. An alternative method of computing drag which takes into account the difference between the upstream and downstream mean pressure yields:

$$D = \frac{\rho k^2}{2\pi\alpha} + \frac{\rho k h}{\alpha}\ (2u_e - u_0) \qquad (5)$$

Equations (3) and (5) are identical if:

$$\coth \pi h/\alpha = \pi h/\alpha \qquad (6)$$

The diffusive decay of vorticity ζ is governed by the well-known diffusion equation (also called the heat-conduction equation):

$$\frac{d\zeta}{dt} = \nu\nabla^2\zeta \qquad (7)$$

which has a solution

$$\zeta = \zeta_0(t)\ \exp\ (-r^2/4\nu t) \qquad (8)$$

The last equation reveals that (1) the vorticity $\zeta_0(t) = k/2\nu t$ at the centre of the vortex decreases inversely with time t, and (2) vorticity spreads, in an interval of time t, over a radius r given by:

$$r^2 = 4\nu t \qquad (9)$$

At an instant of time $t = n/N$ after it is shed, a vortex would have traversed a downstream distance $n\alpha$ and it would have acquired a radius:

$$r = 2(u_0/N)\ (\beta n)^{1/2} \qquad (10)$$

where

$$\beta = \nu N/u_0^2 \qquad (11)$$

is the Lin parameter[3] and equals the ratio of the Strouhal number $S = Nd/u_0$ and the Reynolds number $R = u_0 d/\nu$. The parameter β is independent of the size of the obstacle and depends only on the parameters ν, N, and u_0, and hence it is an inherent property of the vortex-street.

A vortex would be perceptible until $r = h/2$. This yields for the eddy life-time:

$$\tau = \frac{1}{16\beta N}\left(\frac{h}{\alpha}\right)^2\left(\frac{u_e}{u_0}\right)^2 \qquad (12)$$

and the length of the wake:

$$L = \tau u_e \qquad (13)$$

In the laboratory investigations on vortex-streets, the various parameters have the following values:

$$\left.\begin{array}{lll} 0{\cdot}28 < h/\alpha < 0{\cdot}52 & u_e/u_0 \sim 0{\cdot}85 & S \sim 0{\cdot}2 \\ 35 < R < 2{,}500 & 10^{-3} < \beta < 2{\cdot}5\times10^{-3} & \end{array}\right\} \qquad (14)$$

We will now apply the above considerations to the meteorological eddies of Fig. 1. We have selected this particular photograph because it exhibits strong and distinct eddies in a pattern that is more complex than a single two-row vortex-street. A careful inspection of the eddy pattern in the light of the surface analysis 2 h before picture time reveals that there are indeed two vortex-streets generated by the interaction of the airflow with the Tenerife and Gran Canaria islands, respectively.

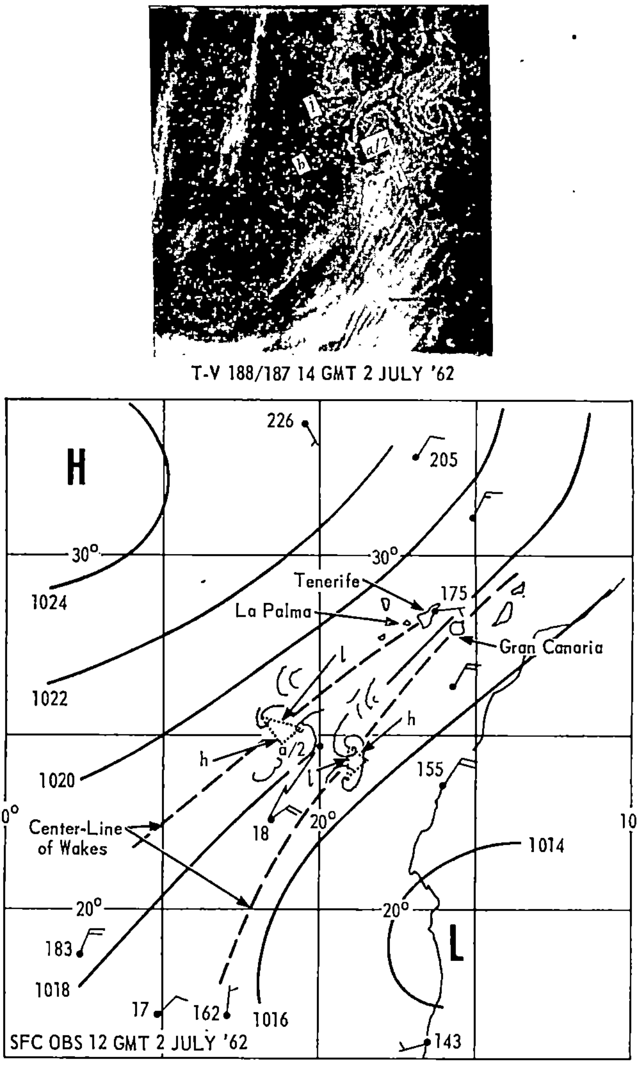

Fig. 1. Complex eddy pattern downstream from Canary Islands 1400 G.M.T. July 2, 1962, *Tiros* V pass 187

It appears from Fig. 1 that the easterly vortex-street is caused by the Gran Canaria Island with a cross-stream diameter $d \approx 35$ mi. The estimated value of the cross-diagonal distance l between two vortices of opposite circulations is 70 mi. Treating the Island as a cylindrical obstacle, it follows from equation (4) that:

$$h \approx 44 \text{ mi.} \quad \alpha = 2(l^2 - h^2)^{1/2} \approx 109 \text{ mi.} \quad h/\alpha \approx 0{\cdot}4 \qquad (15)$$

Again equations (3) and (6) lead to the relation

$$4\pi\left(\frac{h}{\alpha}\right)\left(\frac{u_e}{u_0}\right)\left(1 - \frac{u_e}{u_0}\right) = 1 \qquad (16)$$

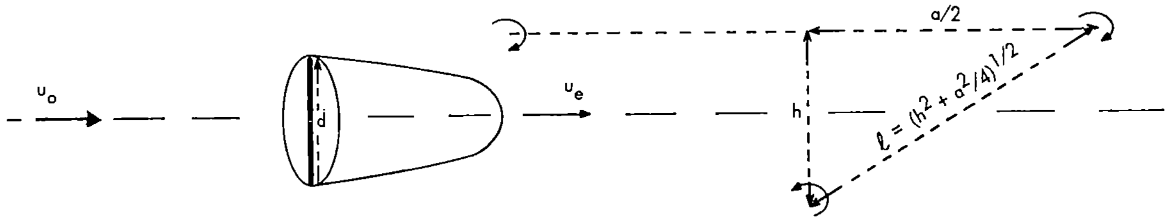

Fig. 2. Schematic diagram of a Kármán vortex-street pattern

which, with the adoption of $u_0 \approx 17$ m.p.h. and substitution for h/α from equation (15), yields:

$$u_e = 0{\cdot}73\, u_0 = 12{\cdot}4 \text{ m.p.h.} \qquad (17)$$

Hence, the frequency of shedding of the eddy-pairs is given by:

$$N \approx 0{\cdot}114/\text{h} \qquad (18)$$

The observed maximum length $L \approx 435$ mi. of the perceptible wake corresponds to $n \approx 4$, which leads to a life-time $\tau \approx 35$ h. These eddies are not always observable during their entire life-time, because certain favourable meteorological conditions, for example, low inversion layer, are essential for making the eddies visible. Therefore, it is of interest to estimate the minimum interval of time the pattern of Fig. 1 would have been discernible to an observer viewing the same area. Since an eddy passed from the upstream edge of the discernible portion of the vortex-street to its downstream edge—a length of approximately $0{\cdot}437L$—the pattern must have existed for at least an interval of time:

$$\tau_{\text{disc}} \approx 0{\cdot}437 \times 35 \approx 15{\cdot}3 \text{ h} \qquad (19)$$

Finally, the estimates of the characteristic parameters β, S, and R, and the coefficient of viscosity ν, are:

$$\left.\begin{array}{l} \beta \approx N\tau \approx \dfrac{1}{16n}\left(\dfrac{h}{\alpha}\right)^2\left(\dfrac{u_e}{u_0}\right)^2 \approx 1{\cdot}3 \times 10^{-3} \\ S = Nd/u_0 \approx 0{\cdot}235 \\ R = S/\beta \approx 178 \\ \text{and} \\ \nu = \beta u_0^2/N \approx 3{\cdot}36 \text{ mi.}^2/\text{h} \approx 2{\cdot}35 \times 10^7 \text{ cm}^2/\text{sec} \end{array}\right\} \qquad (20)$$

Similarly the westerly vortex-street appears to have been caused by the Tenerife and La Palma islands jointly offering a cross-stream diameter $d \approx 36$ mi. with $l \approx 65$ mi. On carrying out an analysis similar to that for the easterly vortex-street, we obtain the following set of values for the various parameters:

$$\left.\begin{array}{lll} h \approx 45 \text{ mi.} & \alpha \approx 94 \text{ mi.} & h/\alpha \approx 0{\cdot}48 \\ u_e/u_0 \approx 0{\cdot}8 & u_e \approx 13{\cdot}6 \text{ m.p.h.} & N \approx 0{\cdot}145/\text{h} \\ L \approx 5\alpha \approx 470 \text{ mi.} & \tau \approx 34{\cdot}5 \text{ h} & \tau_{\text{disc}} \approx 16{\cdot}7 \text{ h} \\ \beta \approx 1{\cdot}82 \times 10^{-3} & R \approx 170 & S \approx 0{\cdot}31 \\ \nu \approx 3{\cdot}6 \text{ mi.}^2/\text{h} & \approx 2{\cdot}55 \times 10^7 \text{ cm}^2/\text{sec} & \end{array}\right\} \qquad (21)$$

The foregoing estimates of the spacing ratio h/α, velocity ratio u_e/u_0, and the parameters S, R, and β are of the correct orders of magnitude for the stable vortex-street patterns observed in the laboratory (equation (14)). The estimate of the eddy viscosity also compares well with other independent estimates made, for example, from experiments on diffusion[4].

The foregoing considerations lead to the following conclusions:

(1) The mesoscale eddy pattern of Fig. 1 is an atmospheric analogue of the Kármán vortex-street observed in the laboratory.

(2) The eddies shown in Fig. 1 are caused by the Canary Islands.

(3) The considerations of the appropriate dimensionless parameters[5] indicate that the eddy viscosity in the atmosphere may be used in the dynamical equations in the same sense as the molecular viscosity is used in the laboratory model experiments to investigate atmospheric phenomena.

(4) The estimate of the eddy viscosity from the above analysis is in agreement with other independent estimates.

(5) A consideration of some practical consequence follows from the observed and expected persistence times of the eddy pattern. If the Canary eddies exist for at least 16 h, the meteorological conditions must also have been steady for that period. This would immediately suggest that if an Earth-synchronous satellite observed such an area continuously, the time-changes of the vortex-pattern would provide a very sensitive indicator of the changing meteorological conditions.

If the foregoing indications (1) and (4) are valid, the loss of momentum to the ocean surface would be smaller than that assumed by Hubert and Krueger[1], and, therefore, it may not be necessary to postulate an instability mechanism to account for the observed long life of the mesoscale eddies.

ICE NUCLEATION AND GROWTH IN SUPERCOOLED WATER FILMS CONDENSED ON A HYDROPHOBIC SURFACE

By DR. HENRY M. PAPÉE, DR. ALBERTO C. MONTEFINALE and DR. T. W. ZAWIDZKI*

Centre for Aerosol Nucleation, National Research Council of Italy, Via Vettore 4, Monte Sacro, Rome

THE mechanism through which a substance may induce a transition of phase from supercooled water to ice[1,2] is still not fully understood, since, although hundreds of compounds have so far been investigated in cloud chambers, conditions at their surfaces seldom appear to have been rigorously monitored. In particular, some aspects of the action of silver iodide still seem to arouse great interest[3]; thus, both the size effect of silver iodide particles on ice-nucleation[4] and the sintering of silver iodide surfaces[5] were investigated in detail, and effects of some surface contaminants on the nucleability of silver iodide were evaluated[6,7]. It was shown, on the other hand, that silver iodide is de-activated by light in its properties of acting as an ice-forming nucleus, and therefore means of protecting the activity of the substance were experimentally sought[1,2].

Photolysis of a surface of silver iodide crystal will result in dissociation of the compound into elements and, what follows, in a progressive collapse of the catalysing surface structure[8]. Although this process will ultimately lead to the de-activation of silver iodide, it was thought[9] that formation of strains and lattice defects during the first moments of irradiation of the surface with light of suitable wave-length will initially activate the compound, because of enhancement of catalysis, due to surface defects and dislocations[10–13]. In order to confirm this hypothesis, we have carried out a series of measurements of ice-nucleability and related lag-times of nucleation, using both ice and silver iodide nuclei which were supported on smooth plates made of an anticorrosive aluminium alloy, 15·0 cm × 15·0 cm and 1 mm thick. The top of the plates was uniformly coated with a layer of 'High Vacuum, Apiezon *L*' stopcock grease. The plates were made to adhere to a copper block, 25 cm × 30 cm of surface, which was hollow and cooled inside to the required temperature, ± 0·2° C, by a fast-flowing stream of 'Antifreeze', which, in turn, was thermo-controlled by means of a standard refrigeration unit. Temperatures of the aluminium plates were obtained, on the basis of suitable calibrations, directly from an electric thermometer placed in the copper block. Only the upper surface of the copper block was exposed and not insulated; a stability of about 0·3° C could have therefore been achieved there, since the room in which the apparatus was mounted was kept at 20 ± 1° C and fluctuations in relative humidity were low (70 ± 10 per cent). Since temperatures at which the experiments were carried out were relatively high (> −12° C) the work was not appreciably affected by side-effects due to foreign matter nuclei in the air; such aerosol was, however, kept at a low level by means of an improvised electrostatic precipitator, which operated continuously in the laboratory.

* Present address: Department of Atmospheric Sciences, Stanford Research Institute, Menlo Park, California.

The development of an ice-spot on an 'Apiezon'-coated aluminium plate from water which condensed there from laboratory air could be satisfactorily monitored from a suitable angle if the plate were properly illuminated. Illumination was provided by a 30-W 6-V microscope lamp, which was situated obliquely to the plate at about 1 m distance and was switched on only for photography, or else by an ultra-violet '*HBO*-200' Zeiss high-pressure-mercury lamp of 600-W input power, which was provided with a quartz collimator and fritted-disk homogenizer, without filters, and which illuminated the plate continuously from the same distance. The experimental procedure was initiated by making a coated plate adhere to the block, after which the plate was fogged by breathing on it, and then allowed to reach thermal equilibrium for about 5 min. Nine groups of nucleation spots were thereafter symmetrically induced on the plates by placing, with a spatula, small mounds of the substance examined on the coated surface, while the procedure was timed. Photography of the growing ice-spot was carried out, using a 16-mm automatic *Ga-Mi* camera, red standard filter and fine-grain 20 *ASA* film; the dimensions of the growing spots were thereafter evaluated by direct examination of the developed film under an enlarger. Fig. 1 shows part of the photographic results of a typical run, while Fig. 2 gives the results obtained on the basis of photographs partly quoted in Fig. 1 and shows the increase of radii in the icing groups, with time.

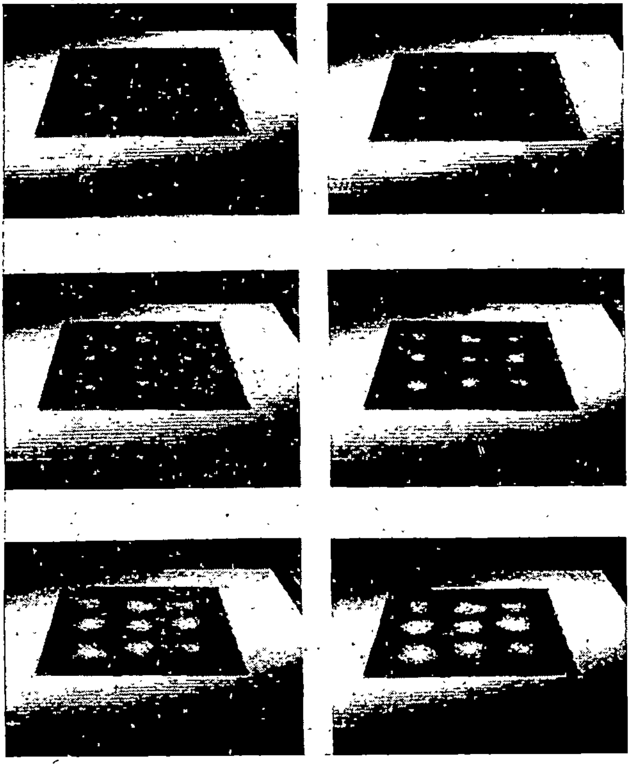

Fig. 1. Ice-spots on 'Apiezon'-coated metal plate, at −2·5° C and at different stages of growth. Timing is about: 600, 1,000, 1,400, 1,800, 2,200, 2,600 sec, respectively, from moment of seeding

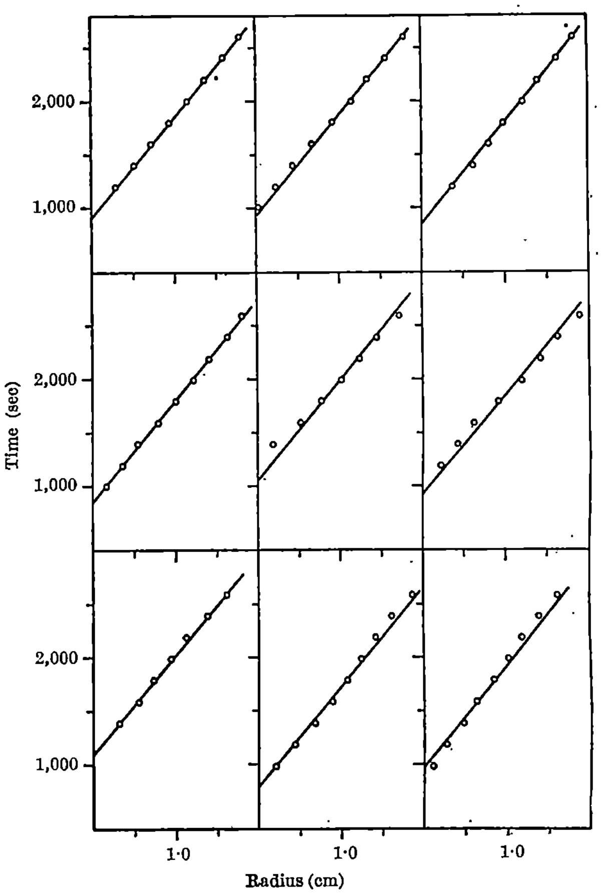

Fig. 2. Plots of times of growth versus 0·5 times diameter (as horizontally 'seen' by camera) of ice-spots shown in Fig. 1. Diagrams emphasize lag-times of nucleation of silver iodide; the experiment was carried out under ultra-violet illumination. Cumulative linear regression on all lines assumes common gradient[14]

Freshly ground, commercial silver iodide, 99 per cent pure, which was desiccated 24 h at 110° C in a stove and afterwards ground to pass through an A.S.T.M. screen of 140 mesh/in., or, alternatively, ice which condensed on the copper block, were used under conditions of illumination described here for the 'seeding' of plates.

The spread of icing after nucleation appears to be approximately linear with time in our experimental conditions; hence its rate can be obtained from the gradients of the plots, such as shown in Fig. 2, while the lag-time of nucleation inherent to the substance examined may be evaluated from the intercepts. The rates were calculated from gradients common to the lines obtained at the same conditions and were plotted against the temperature of operation in order to evaluate the change of the rates of growth with temperature (deg. C). The plots obtained from experiments where ice-growth was initiated

Table 1. TEMPERATURE DEPENDENCE OF RATES OF GROWTH OF ICE ON 'APIEZON', UNDER TWO DIFFERENT CONDITIONS OF ILLUMINATION AND WITH TWO DIFFERENT SEEDING AGENTS

Nuclei	Illumination	Rate of ice-growth (cm/sec/°C × 10^4)
AgI	Tungsten	2·46 ± 0·04
Ice	Tungsten	2·52 ± 0·07
Cumulative	Tungsten	2·48 ± 0·04
AgI	Ultra-violet	3·37 ± 0·1
Ice	Ultra-violet	3·71 ± 0·2
Cumulative	Ultra-violet	3·54 ± 0·1

either with ice or with silver iodide nuclei are shown in Fig. 3, and the results are summarized in Table 1.

While the time of lag in nucleation appeared to be approximately nil in the case of freezing initiated with ice, as substantiated by a symmetrical distribution, with a standard deviation of 50 sec, of extrapolated values about the r axis, the behaviour of silver iodide is quite different, as shown in Fig. 4. The experimental values appear to follow here a monotonic increase with temperature; the plot can satisfactorily be fitted (see later) with a function of the type:

$$t = \frac{\alpha}{\Delta T}\, e^{-\beta \Delta T} \qquad (1)$$

where t = lag-time of nucleation (sec); this quantity is taken as an average of individual lag-times of n spots which nucleated out of the total of nine spots, multiplied by $9 : n$; ΔT = the difference (deg. C) between T_0, the highest temperature at which the substance will nucleate ice, and the temperature of operation, T; α and β = constants, which can be estimated by linear regression if ΔT is known.

We are aware that the experimental method, such as described here, of estimating ice-nucleating power and lag-time of action of different substances may be subject to several refinements. However, although this work was carried out mainly with the object of finding and testing fast and reliable means of evaluating ice-nucleating properties of diverse compounds without having to disperse them as aerosols, some preliminary observations of a more fundamental nature can already be made at this time. The rates of growth of nucleated ice-layers appear, in our experimental conditions, to be in fair agreement with the order of magnitude of values derived by Burton, Cabrera and Franck, as discussed by Mason[15]; they differ, however, from values proposed by Hillig and Turnbull[16], probably due to the effects of the substrate on which such growth occurs[17] and to the structure of the growing ice-surface[18,19] and related effects[20], as substantiated by faster rates of growth under ultra-violet radiation. The lag-time of ice nucleation of a substance may, in our experimental conditions, be expressed in terms of the difference between the temperature at which the substance nucleates, and the temperature of operation. If equation (1) is resolved in series for small values of ΔT, there is approximate proportionality between t^{-1} and ΔT, and hence the value of T_0, the highest temperature at which a substance will act as a freezing nucleus, may be obtained by extrapolation (Table 2).

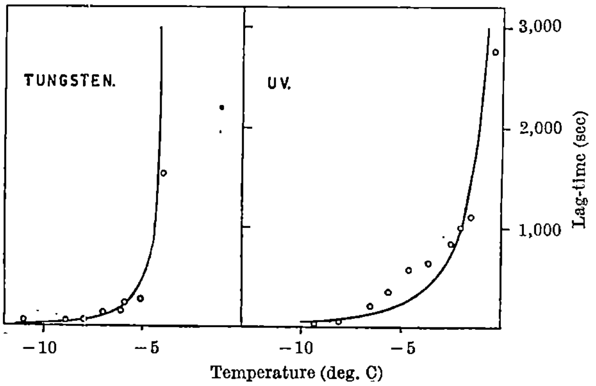

Fig. 4. Lag-times of nucleation of ice on 'Apiezon', for identical silver iodide product, under tungsten and ultra-violet light; experimental points were fitted with function of type given in equation (1); parameters are given in Table 2

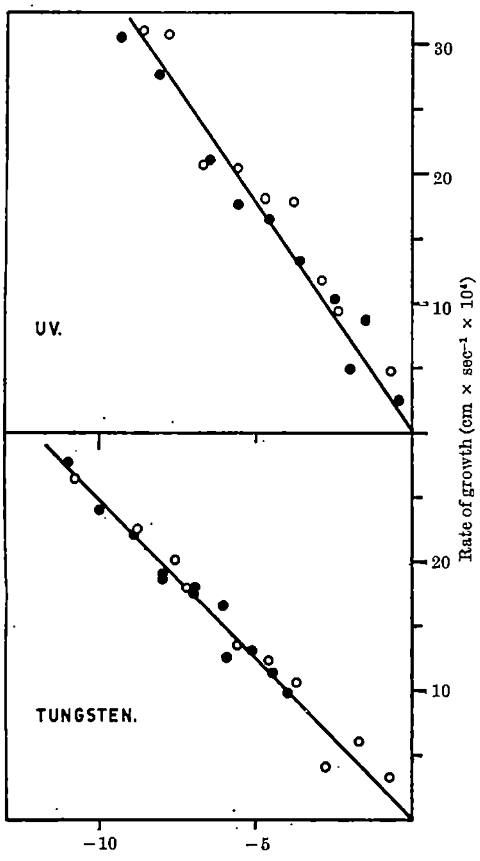

Fig. 3. Growth of nucleated ice-spots on 'Apiezon' substrate, as function of temperature. Full and empty circles stand for experiments where silver iodide and ice, respectively, were used for 'seeding' of plates. Regression was made to force lines through origin

Table 2. CONSTANTS OBTAINED FROM CURVE-FITTING PROCEDURE ACCORDING TO EQUATION (1), AND HIGHEST EXPERIMENTAL TEMPERATURES OF NUCLEATION OF SILVER IODIDE, FOR BOTH TYPES OF ILLUMINATION

Illumination	Correlation coefficient, t^{-1} versus $T(-6–0°C)$	T_0 (°C) Calculated	T_0 (°C) Used for curve fitting	T_0 (°C) Highest experimental	α	β
Tungsten	−0·97	−3·9 ± 0·2	−3·9	−4·0	726	0·260
Ultra-violet	−0·97	+0·4 ± 0·5	0·0	−0·4	2,763	0·168

Both Fig. 4 and Table 2 reveal an effect of ultra-violet radiation on the nucleating power of freshly ground and desiccated silver iodide, indicating, in agreement with what was stated in ref. 9, that the activity of a crystal of silver iodide may first be enhanced by short-wave light, and only afterwards destroyed by photolysis.

We thank Prof. V. Caglioti for advice. This work was supported in part by 'Cassa per il Mezzogiorno'.

SEGRÉ-SILBERBERG ANNULUS FORMATION: A POSSIBLE EXPLANATION

By R. V. REPETTI and Prof. E. F. LEONARD

Department of Chemical Engineering, Columbia University, New York

SEGRÉ and Silberberg, working with a neutrally buoyant dilute suspension of rigid spheres, were first to report the formation of an annulus of spheres concentric with the tube axis during laminar flow through a vertical duct of circular cross-section[1]. Their result, described in detail elsewhere[2], was unexpected because prior investigations of radial particle displacements in Poiseuille flow had suggested only the possibility that particles could move radially inward, that is, from the wall toward the tube axis.

We are at present examining the radial motion of single rigid spheres in a laminar flow contained in a vertical duct and have observed particles that drifted all the way from the wall to the tube axis while others have done the reverse. Still others have exhibited no radial drift or have drifted either a short distance in from the wall or a short distance out from the axis, a condition analogous to that required by the Segré-Silberberg effect.

We believe these phenomena can be explained as follows: Rubinow and Keller[3] have shown that a rotating sphere moving with velocity V through a viscous unbounded fluid is acted on by a lift force F given by:

$$F = \pi a^3 \rho_f \Omega \times V \qquad (1)$$

where a is the sphere radius, ρ_f is the fluid density, Ω is the angular velocity, V is the difference between the transverse velocities of the fluid and particle and F is the lift force perpendicular to the plane of Ω and V. This equation was not derived for a Poiseuille flow, but, as Rubinow and Keller point out, there is reason to believe that it yields a force of the correct order of magnitude for such a flow. This assumption was supported by the results of a test we applied to the data of Goldsmith and Mason[4] for rigid spheres in a Poiseuille flow at very low Reynolds numbers. (Equations (1), (2) and (5) of this article were combined to give another describing the radial lift force on the sphere. Radial acceleration was neglected and the differential equation describing radial motion of the sphere was obtained by equating the lift force to the Stokes drag, $6\pi\mu a(\mathrm{d}r/\mathrm{d}t)$. Simultaneous solution of the differential equations of radial and axial motion resulted in predictions of particle trajectories which for the small radial migrations reported by Goldsmith and Mason resulted in predicted axial travels greater than those observed by a factor of 5·2 at most, and by a factor of 2·7 on the average. Similar results are obtained for particles in the system we are investigating (described elsewhere in this article), a system considerably different from that of Goldsmith and Mason.) Accordingly we apply equation (1) here, bearing in mind the reservations associated with its use. The required rotational and transverse velocities are consequences of the parabolic velocity distribution as is shown below for the case of a neutrally buoyant system.

The gradient of the velocity profile is responsible for the angular velocity of the particle. If one restricts consideration to spheres the diameter of which is small compared with the radius of curvature of the velocity profile, Ω can be approximated by a relationship given by Jeffery[5]:

$$\Omega = -\frac{v_m r}{R^2} \qquad (2)$$

where v_m is the maximum (centre-line) velocity within the tube, r is the distance from the axis to the sphere centre and R is the tube radius.

Goldsmith and Mason[6] have presented evidence showing that for rigid spheres the difference between actual particle velocity and the fluid velocity that would prevail at the location of the sphere centre increases as $\frac{r}{R}$ increases, with the sphere lagging behind for all $\frac{r}{R}$. Their results, obtained from several systems, when put in non-dimensional form, give a general curve, which we have approximated by:

$$\frac{v_f - v_p}{v_m} = \frac{2}{3}\left(\frac{a}{R}\right)^2 \left[A\left(\frac{r}{R}\right)^4 + B\left(\frac{r}{R}\right)^2 + C\right] \qquad (3)$$

where v_f is the fluid velocity that would prevail at the sphere centre were the sphere not there, v_p is the actual axial particle velocity, and the constants A, B and C have the values 3·04, 1·58 and 1·00. Dr. Mason has kindly furnished additional data points[7] which fall slightly above this curve, and he points out that one would expect factors such as the Reynolds number to affect the position of the curve. However, we shall see that the important feature of equation (3) is its dependence on $\frac{r}{R}$, and Dr. Mason's additional results also exhibit this dependence.

With the above means of approximating the particle velocity, a decision is now required as to what fluid velocity to compare it with in order to obtain V. Since the fluid velocity is different at various points surrounding the sphere, some form of average velocity is suggested. Consider the moving particle to sweep out a tube of fluid within the paraboloid describing the velocity distribution in the duct. The presence of the sphere will influence the fluid to some distance δ past the sphere surface. If one computes the average velocity v_{af} of the fluid within this tube of radius $(a+\delta)$ for any position of the tube within the duct, the result is:

$$v_{af} = v_m\left[1 - \left(\frac{r}{R}\right)^2 - \frac{1}{2}\left(\frac{a+\delta}{R}\right)^2\right] \qquad (4)$$

Since $v_f = v_m\left[1 - \left(\frac{r}{R}\right)^2\right]$, it follows that:

$$V = v_{af} - v_p = \frac{2}{3}\left(\frac{a}{R}\right)^2 v_m\left[A\left(\frac{r}{R}\right)^4 + B\left(\frac{r}{R}\right)^2 + C\right] - \frac{v_m}{2}\left(\frac{a+\delta}{R}\right)^2 \qquad (5)$$

The following considerations apply in the selection of a value for δ: when $\delta = 0$, V is positive for all $\frac{r}{R}$. In terms of a co-ordinate system fixed on the duct centre-line in which the positive axial direction is with the flow, a positive V together with the negative value of Ω from equation (2) would give a negative, or inward-directed force on the sphere as determined by the vector cross-product of equation (1). If δ is assigned increasingly larger values (as defined, δ cannot be negative) the value of V for any $\frac{r}{R}$ is decreased from its $\delta = 0$ value until at $\delta = 1{\cdot}15a$ V becomes zero. Further increases in δ result in negative V near the tube axis and a corresponding shift in the $V = 0$ point toward the tube wall. Negative values of V are associated with particle drift away from the tube axis, again as dictated by the vector cross-product of Ω and V. Thus, if δ were in fact greater than $1{\cdot}15a$, one would predict the existence of a region near the tube axis in which particles would seek to move away from the axis and to accumulate at the value of $\frac{r}{R}$ for which $V=0$. Similarly, particles near the wall (where V is positive) would move inward, also seeking the position for which $V=0$. When $V=0$ the radial force is zero and this consideration determines the site of the Segré-Silberberg annulus.

The choice of δ therefore influences the prediction of where the annular zone would form. (The accumulation site is also influenced by the fluid velocity distribution. In a two-dimensional parabolic field (as ideally between broad flat plates or as approximated by a duct of rectangular cross-section of large aspect ratio) the coefficient of $(a+\delta)^2/R^2$ in equation (4) is 1/4 instead of 1/2. This produces the result that, for a given value of δ, the accumulation site would occur, if at all, closer to the axis than it does within a duct of circular cross-section.) In actuality δ is possibly even a function of $\frac{r}{R}$, but is here assumed constant for simplicity. Dr. Mason's results, which demonstrated drift in either direction[7], were best correlated by assuming $\delta=a/2$. When V is plotted against $\frac{r}{R}$ for $\delta=a/2$ a curve such as Fig. 1 is obtained where $V=0$ corresponds to $\frac{r}{R}=0·53$. This value agrees reasonably well with that reported by Segré and Silberberg.

Our observation that particles could move in either direction over the entire distance between the wall and the tube axis has a similar explanation. The density of these particles was about 0·1 per cent different from that of the fluid. Consequently a buoyancy term, independent of position within the duct and approximated by the Stokes settling velocity, must be added to the value of V. A particle less dense than the fluid could therefore be described by a curve similar to Fig. 1, only shifted upward in its entirety by an amount equal to the Stokes velocity. A sufficiently large buoyant velocity could make the curve everywhere positive and thereby give a force directing the particle toward the tube axis for all values of $\frac{r}{R}$. Similarly, a sphere more dense than fluid in downflow through a vertical tube could be driven out to the duct wall.

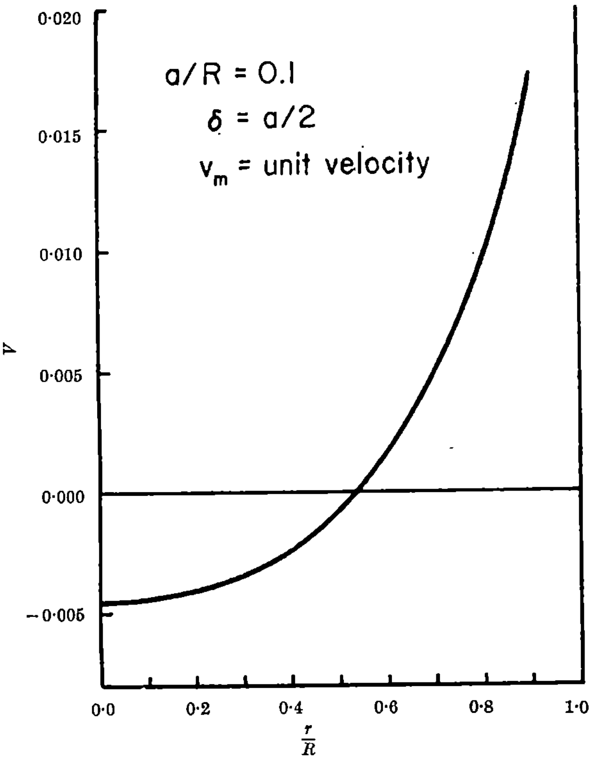

Fig. 1. Typical plot of velocity difference between sphere and fluid versus radial position. Where V is negative, particle moves faster than surrounding fluid and drifts outward, whereas for positive V the reverse is true. $V=0$ represents stable equilibrium point

Experimentally we have readily produced these phenomena in a system of single nylon spheres within a flowing aqueous sodium chloride solution. The small density differences required to change the drift direction are obtained either by changing the system temperature (usually less than 5° C) degrees for a given sphere density, or by the addition of either more salt or water to the fluid.

A typical result with three spheres of 0·476 cm diameter and only slightly different densities released at different times from a position of $\frac{r}{R}=0·2$ within a long vertical duct of rectangular cross-section showed the following: after 66-cm axial travel a nearly neutrally buoyant sphere had drifted to $\frac{r}{R}=0·47$, a second sphere 0·04 per cent more dense than the first had drifted to $\frac{r}{R}=0·66$ and a third 0·06 per cent less dense than the first had drifted to $\frac{r}{R}=0·25$ These values do not represent equilibrium positions and are cited for the purpose of illustrating the effect of small density differences. (Cross-section dimensions are 2·54 cm × 10·16 cm and duct-length is 2·5 m, the lower 66 cm of which are used for experimental observations. Drift is examined between the narrowly separated walls and is confined to the mid-plane between the other walls. In the example cited, R therefore equalled 1·27 cm and the fluid flow rate was 50 cm³/sec.)

Oliver[8] has reported similar experimental results and furthermore has concluded that particle rotation causes movement to the wall while the absence of rotation causes motion away from the wall. Equation (1) here appears to require that both particle rotation and slip be present simultaneously in order that a lift force may exist. Oliver observed drift with no rotation, however, and we have found that non-rotating particles could drift either toward or away from the duct wall. (Spheres were drilled with small shallow holes which were then filled with wax so that the particle remained spherical in shape, but with a displaced centre of gravity. The fluid density was then adjusted so that it either equalled or was slightly different from that of the particle.) The explanation of the apparent discrepancy between equation (1) and observation is that the equation is of the same type as the more general Kutta-Joukowski equation for infinitely long cylinders in which the lift is related to the cross-product of the fluid circulation and the transverse velocity difference. As Tollert[9] points out, circulation can arise with a translating sphere either by sphere rotation or by unsymmetrical streaming about the non-rotating sphere. The Rubinow-Keller stationary viscous fluid required that the particle rotate in order that the circulation be non-zero, with the circulation in effect being approximated by a function of the particle angular velocity. In a Poiseuille flow, however, the velocity distribution produces a non-zero circulation by virtue of the unsymmetrical streaming about the sphere. (This was demonstrated by filling several small shallow holes in a non-rotating sphere with potassium permanganate. As the sphere was carried along by the fluid, two easily visible permanganate streams emanated from it: one leading the sphere and which left its surface on the duct axis side of the sphere centre and one trailing the sphere and which left the surface on the wall side of the sphere centre.) Hence one would expect particle drift to be possible in either direction anywhere in the tube except at the axis where, because of symmetry, the circulation vanishes to zero. This requirement confirms the intuitive feeling regarding the importance of particle shape as a factor in influencing drift rate, because of the way in which streaming around the body and hence circulation is shape-dependent. Equation (1) is therefore to be regarded as only an approximation in which the circulation is in turn approximated by a function of the fluid velocity gradient. Dryden[10], in discussing the circulation about rotating cylinders, referred to the discrepancy between theory and experiment and concluded that accuracy requires actual measurement of the circulation, a comment that sheds light on the likelihood of developing a single accurate expression for predicting drift rates for particles of different shapes and surface conditions.

In summary, the foregoing analysis has described the factors producing radial drift and has proposed a means by which the Segré-Silberberg annular zone could be formed. Experimentally we have qualitatively confirmed all modes of drift predicted for a system flowing down a vertical duct. We are now seeking to compare quantitatively the observed trajectory with the predicted trajectory based on the radial force obtainable by a combination of equations (1), (2) and (5).

SEPARATION OF HYDROCARBON LIQUIDS BY FLOW UNDER PRESSURE THROUGH POROUS MEMBRANES

By Dr. S. SOURIRAJAN

Division of Applied Chemistry, National Research Council, Ottawa

THE selective permeation of hydrocarbon mixtures through non-porous polymeric films has been examined extensively[1-12]. In these investigations the feed is usually in the liquid state, the film is held in the swollen state by heating and the permeated product is withdrawn as a vapour and afterwards condensed. On the other hand, Kammermeyer and Hagerbaumer[13] established the feasibility of the liquid phase separation of several hydrocarbon mixtures by pressure permeation through microporous glass having an average pore diameter of 40 Å.

The concept of preferential sorption at the fluid-membrane interface together with the flow of the interfacial fluid through capillary pores of size equal to, or less than, a critical diameter characteristic of the system offers a new approach to the development of a general industrial process for the separation of hydrocarbon mixtures. The experimental technique consists simply in letting the fluid mixture flow under pressure through an appropriate porous membrane; the membrane-permeated fluid is enriched in the preferentially sorbed constituent. No heating of the membrane and no phase change in product recovery are involved in this separation process.

The governing criteria of this process may be stated as follows. An appropriate chemical nature of the film surface in contact with the solution, together with the existence of pores of appropriate size on the area of the porous film at the interface, is an indispensable twin requirement for the success of this separation technique. Further, the rate of fluid permeation through the membrane can be increased, without affecting the degree of separation under the given operating conditions, by simply increasing the number of pores of the appropriate size on the film surface. Thus, for any given membrane material, the obtainable degree of separation and the rate of fluid permeation are two independent characteristics of the film, which can be varied by varying its porous structure.

From an industrial point of view, the application of the above technique for a given separation problem involves essentially the problem of choosing the appropriate chemical nature of the film surface and developing techniques for making films containing the largest number of pores of the required size on the area of the film at the interface. This approach formed the basis of the successful development of porous cellulose acetate membranes capable of giving both high flow rates and high degrees of demineralization of aqueous sodium chloride solutions[14]. The general applicability of the foregoing technique for the separation of inorganic and organic substances in aqueous solution, as well as for the separation of gases, has already been demonstrated[15-18]. This communication is concerned with its applicability for the separation of liquid hydrocarbon mixtures.

Three different types of porous films, designated here as *S and S*, *CA* and *PE* films, were used in these experiments. The *S and S* films are the commercially available cellulose acetate ultrafine filter membranes, type *UA*-superdense, supplied by Carl Schleicher and Schuell Co. The *CA* films are porous cellulose acetate membranes made in the laboratory by the method described earlier[14] using the following composition (weight per cent) for the film casting solution: acetone, 68·0; cellulose acetate, 17·0; water, 13·5; magnesium perchlorate, 1·5. The *S and S* and *CA* films have similar, but not identical, relative separation characteristics, and hence they are classified separately. These films were initially shrunk by immersion in hot water, and then washed in successive dishes of absolute alcohol. The *PE* films are porous polyethylene films made in the laboratory by a special method, details of which will be published at a later date. The feed solution systems tested were xylene-ethyl alcohol, xylene-*n*-heptane and *n*-heptane-ethyl alcohol. Just before use in the experiment, the films were dried between filter papers, and quickly immersed in the feed solution and again dried superficially between filter papers. The operating cell is a stainless steel pressure chamber consisting of two detachable parts. The film is mounted on a stainless steel porous plate embedded in the lower part of the cell through which the membrane permeated liquid leaves the system at the atmospheric pressure. The upper part of the cell contains the feed solution under pressure in contact with the membrane. The two parts of the cell are clamped and sealed tight using rubber O-rings. Compressed nitrogen gas was used to pressurize the system. The experiments were conducted under static conditions at the laboratory temperature. A new sample of the film was used for each experiment. The quantity of liquid removed by membrane permeation was small compared to the amount of feed solution in the pressure chamber. The compositions of the feed and the membrane permeated liquids were analysed by means of a Bausch and Lomb precision refractometer capable of giving refractive index data within an accuracy of 0·00003, which corresponds to an accuracy of better than ±0·1 per cent for the systems tested in this work.

A set of experimental results is given in Table 1 and Fig. 1. The results illustrate the fact that the separation technique was successful in all the cases tested. For the feed system xylene-EtOH, the *S and S* and *CA* films have preferential sorption for EtOH, and the *PE* films exhibit preferential sorption for xylene. Further, when the surface of the *S and S* film was sprayed uniformly with 'Fluoro-glide' (a fluorocarbon polymer supplied by Chemplast, Inc.) and used in contact with the above feed system, the direction of separation was reversed. This latter observation again shows[19] that the mechanism of the process is governed by a surface phenomenon. For the system xylene-*n*-heptane, all three types of films used exhibit a preferential sorption for xylene. For the system *n*-heptane-EtOH, the membrane permeated liquid shows alcohol enrichment for the *S and S* and *CA* films and *n*-heptane enrichment for the *PE* films ; the data also illustrate that azeotropic composition is no limitation to this separation process. The chemical nature of the membrane surface determines the direction of separation for a given feed system. The separation and flow rate data given here do not set the limits of those obtainable for the types of films used, but they illustrate that different levels of separation and flow rates are obtainable for the same membrane material depending on the porous structure of the films used. Fig. 1 shows the effect of operating pressure on the separation and flow characteristics of a *CA* film for the system *n*-heptane-EtOH. The variation of flow rate of the membrane permeated product with pressure, considered together with the corresponding alcohol-enrichment in the product, indicates that the process involves capillary flow of the liquid through the porous film.

Table 1

Area of film surface: 7·9 cm². Operating pressure: 1,000 p.s.i.g.

Exp. No.	Feed liquid composition (mole %)		Film type	Membrane-permeated liquid Composition (mole %)		Flow rate (g/h)

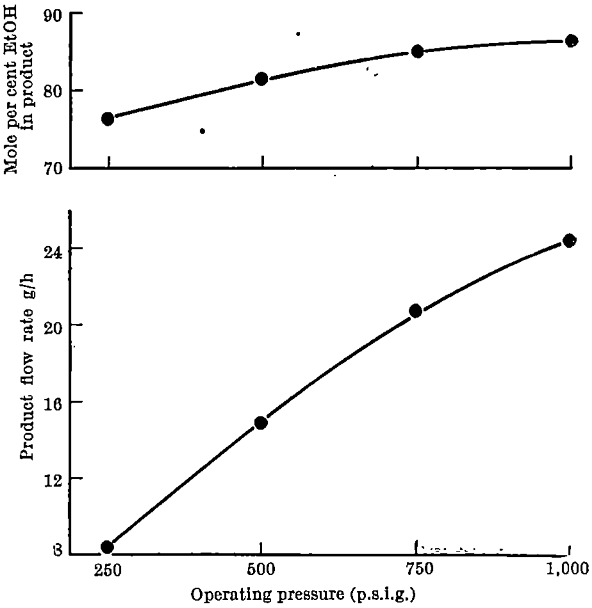

Fig. 1. Effect of operating pressure on the separation and flow characteristics of a *CA* film. Area of film surface, 7·9 cm²; feed composition (mole per cent): *n*-heptane, 33; EtOH, 67

The experimental results presented in this paper and those reported earlier[15–18] demonstrate the general applicability of the foregoing technique for the separation, concentration or fractionation of inorganic or organic substances in aqueous or non-aqueous solutions in the liquid or the gaseous state, and open a new and versatile field of separation technology in chemical process engineering. A precise understanding of the physicochemical criteria of preferential sorption (or preferential repulsion) of substances at interfaces, and the mechanism of pore formation in the process of casting high-flow porous films is, however, needed to develop this technology to its fullest industrial potential. Already it is clear that the high flow porous cellulose acetate membranes developed in connexion with saline water conversion[20] can also be profitably used in separation processes involving a wide variety of aqueous solutions as well as mixtures of hydrocarbon liquids.

I thank Dr. I. E. Puddington and Dr. G. L. Osberg for their advice, Messrs. W. S. Peterson, A. E. McIlhinney and Neil H. Scheel for their help in building the equipment, and Lucien Pageau and A. G. Baxter for their assistance.

RELATION OF PROTEIN EVOLUTION TO TERTIARY STRUCTURE

By DR. CHARLES J. EPSTEIN

Laboratory of Chemical Biology, National Institute of Arthritis and Metabolic Diseases, Bethesda, Maryland, and Division of Medical Genetics, Department of Medicine, University of Washington School of Medicine, Seattle

THE recent advances in the determination of the amino-acid sequences and the three-dimensional configurations of proteins have provided a great impetus to the examination of the evolution of proteins, or 'chemical palæogenetics'[1]. When one compares proteins which are closely related in configuration and function but differ significantly in their amino-acid sequences (as, for example, the several chains of hæmoglobin), it is of great interest to determine whether there are any basic principles that governed their evolution. Two stages of protein evolution may be arbitrarily defined. The first involves the assembly of amino-acids into a 'primitive protein', such as the postulated 'primitive chain' of hæmoglobin, which has a definite configuration and function (whether enzymatic, structural, transport, or other). In terms of evolutionary chronology, this is probably by far the longer stage. During the second stage of evolution, with which this article is concerned, the 'primitive protein' undergoes divergent evolution, presumably by a process of random mutations and natural selection (of the organism in which it is found), so that several distinct proteins (in the same or different species) with similar structures and activities are produced.

It is now generally believed that the specific conformation that a polypeptide chain assumes in the formation of a 'native' protein is determined principally by its amino-acid sequence[2]. This being the case, for a 'mutant' or 'evolved' protein to preserve its original function, two requirements must be met. First, it is necessary that the few critical residues directly involved in activity or function remain intact (or that adequate substitutes be provided). Second, the polypeptide chain must be capable of folding in a way that will bring these residues into the proper relationship to one another. Therefore, an enquiry into the principles which govern the evolution of homologous proteins from common precursors becomes, in a large measure, an investigation of the factors which govern the folding of proteins.

On the basis of investigations of the chemical and X-ray crystallographic properties of myoglobin[3,4], a simple but important generalization has been made: most, but not all, of the polar residues appear to be located on the surface of the molecule, while most of the non-polar (hydrophobic) residues are found in the interior of the molecule. The results obtained from the experimental modification of ribonuclease[5,6] and trypsin[7] are in agreement with these ideas. The only major exception, in the case of myoglobin, involves glycine and alanine, these residues being frequently located on the surface. On the basis of these observations, the following hypothesis was recently advanced[8]: during the evolution of homologous proteins, amino-acid substitutions (or 'exchanges' or 'transitions') will be permissible (that is, will allow for proper folding of the protein) if they involve interchanges between one polar residue and another, between one hydrophobic residue and another, or (in some cases) between a polar residue and glycine or alanine: exchanges between polar and hydrophobic residues will not be permissible. This hypothesis is derived, of course, from the supposition that during the folding process polar residues will tend to seek out the surface of the molecule while hydrophobic ones will seek out the interior. Therefore, if a non-permissible substitution is made, a residue destined for the surface might now seek out the interior, or vice versa, thereby interfering with the correct folding of the molecule.

These 'rules' must be considered in two contexts. The first involves situations in which the homologous proteins differ by only one or a very few amino-acid residues. In such cases, it is quite conceivable that a small number of non-permissible exchanges might not be able to negate the overwhelming influence of the remainder of the residues and would not, therefore, interfere with the formation of the proper tertiary structure. On the other hand, when two homologous proteins differing significantly in their amino-acid sequences are compared, it would be expected, if the hypothesis is correct and if structural and functional integrity is to be preserved, that the 'rules' should hold quite firmly for the aggregate of the amino-acid exchanges. It should also be realized that other unknown 'rules', possibly not always fully compatible with the hypothesis under consideration, may be involved in protein evolution. Furthermore, it is quite apparent that the present hypothesis represents a simplification of the process of protein evolution and of the mechanics of polypeptide chain folding ignoring, as it does, the role of factors such as electrical charge and the size and shape of the various amino-acid residues.

In order to test the hypothesis stated here, the following question was asked: in comparing related proteins, that is, proteins with similar functions and with sufficient homologies in amino-acid sequence to ensure that they are derived from common precursors, how often are the observed amino-acid exchanges of a permissible type, and how often are they not? To facilitate the analysis, the specific amino-acid differences between pairs of homologous proteins for which complete primary structure data were available were placed in one of three categories: (I) permissible: polar/polar or hydrophobic/hydrophobic interchanges; (II) possibly permissible: polar/glycine or polar/alanine interchanges; (III) non-permissible: polar/hydrophobic interchanges.

The assignment of residues to the polar or non-polar groups has followed the usage of Kendrew[3], and tyrosine and tryptophan have been considered as polar residues; cysteine, which is only rarely involved in an exchange, has been considered as non-polar. Accordingly, interchanges between phenylalanine and another aromatic amino-acid have been placed in category III, although it is quite conceivable that they could be considered as permissible in many instances (particularly phenylalanine/tyrosine interchanges).

In order to evaluate the significance of the results obtained, it is necessary to have a standard for comparison. Ideally, one would like to know the single and multistep mutations that are actually (chemically) possible on the basis of the nucleotide amino-acid 'code words'. Unfortunately, such data are not yet available. Experimentally produced single-site mutations are still too few in number and such information would, in general, not be applicable. This is because of the fact that, in most cases, only those mutations which are compatible with the recognition and isolation of the mutant proteins are observed, thereby eliminating from consideration those mutations that might be chemically feasible but structurally impossible.

Because of these difficulties it was thought reasonable, in this preliminary analysis, to compare the observed

Table 1. Analysis of Observed Amino-acid Exchanges

	Authors* (refs.)	Total ex-changes	Type of exchange			Assuming exchanges of type I + type II are permissible				Assuming exchanges of type I + 1/2 × type II are permissible			
			I	II	III	Permis-sible	Non-per-missible	χ^2	P	Permis-sible	Non-per-missible	χ^2	P
Expected random frequencies						60%	40%			54%	46%

frequencies of the various categories of exchanges with the frequencies which would be expected on the basis of random exchanges between any two of the twenty amino-acids (without utilizing any specific information relating to the amino-acid 'code'). By the latter method, the 'random' frequencies of the three categories of exchanges were found to be: type I, 48 per cent; type II, 12 per cent; and type III, 40 per cent. When these data were weighted for the actual amino-acid composition of a protein such as the hæmoglobin β-chain, the frequencies obtained were very nearly the same.

Two different methods have been used to compare the random expectations with the observed frequencies. The first method (method *A*) is based on the assumption that all type II exchanges will be permissible, that is, that type I + type II = permissible exchanges, and type III = non-permissible exchanges. Thus, the frequency of randomly-expected permissible exchanges will be 48 per cent + 12 per cent = 60 per cent, and of non-permissible exchanges, 40 per cent. These values may then be compared with the observed data (in which type I and type II exchanges are similarly combined), and the results analysed statistically by the χ^2 method (with the Yates correction for continuity). The second method (method *B*) of comparison makes use of the more rigorous assumption that, on the average, only half of type II exchanges are actually permissible (for example, in specific instances, a polar-glycine might be while an alanine-polar might not). The random frequencies then become: permissible = I + 1/2 × II = 48 per cent + 1/2 × 12 per cent = 54 per cent; non-permissible = 1/2 × II + III = 1/2 × 12 per cent + 40 per cent = 46 per cent. As with method *A*, these values may then be compared with the similarly treated observed frequencies. If the observed and random-expected frequencies are significantly different, we may consider this as evidence in support of the hypothesis.

The major problem in actually testing the hypothesis by these methods is to find suitable sets of homologous proteins for examination. So far, complete sequence data are available for relatively few proteins, and for still fewer sets of homologous proteins. However, the pairs listed in Table 1 were considered to be suitable for analysis. In comparing the α- and β-chains of human hæmoglobin with one another, and the hæmoglobin chains with myoglobin, it has been necessary to compensate for deletions or additions of amino-acids. Because of the large number of identical regions in the two chains, no difficulty is encountered in the former instance, but when comparing myoglobin with hæmoglobin, it was necessary to make assumptions about homologous regions. The hæmoglobin–myoglobin analogies are based on the myoglobin sequence of Edmunds and Kendrew as quoted by Schroeder[9].

The results of the various analyses are shown in Table 1. For the hæmoglobin α/β, β/γ, and the human/primate β-chain comparisons, the observed frequencies of the various types of amino-acid exchanges are significantly different from random, by both methods of computation. For the human/horse α-chain comparison, the results are significant by method *A*, and by both methods for the myoglobin/hæmoglobin chain comparisons. In the case of the insulin comparison (human and bonito insulins being compared because they appeared to be the most divergent), the number of interchanges is small and there is a rather high proportion of non-permissible exchanges. One wonders whether these two proteins might prove to have significant differences in tertiary configuration. The total number of residues involved in the comparison of human and horse cytochrome *c* is small, and the observed frequencies are not statistically significantly different from random. On the other hand, the comparison of horse heart and baker's yeast cytochrome *c* and of tuna fish and yeast cytochrome *c* (proteins derived from species that are certainly quite distant) shows that type I exchanges far outnumber type III. The differences are highly significant by both methods for the tuna fish/yeast comparison, but do not reach statistical significance for the horse/yeast comparison.

The analysis of series of homologous proteins in which only a small number of differences are found presents considerably more of a problem. While it is easy to determine the category in which to place the single-site mutations of human hæmoglobin, it is much more difficult to handle groups of proteins in which more than two amino-acid residues are found at the same site. Examinations of such groups of proteins and also of physiological peptides and protein fragments have been made by Yčas[10], by Eck[11], and by Šorm[12]. If we evaluate the results obtained by these authors, we find that type I exchanges are by far the most common, and that type III are generally the least frequent. However, because of the difficulties inherent in interpreting these comparisons, only the results of the analysis of the human hæmoglobin single-site mutations are included in Table 1. For these exchanges, the results are significantly different from random expectation, by method *A*, even though the numbers are small. Finally, if all the data in Table 1 are pooled, the distribution of exchanges is significantly different from random, with $P < 0·001$, by both methods of comparison.

The outcomes of the various hæmoglobin and myoglobin comparisons are particularly instructive, since for these proteins we have information regarding their tertiary configurations in addition to their amino-acid sequences. As has been previously pointed out, these proteins are quite similar, although certainly not identical, in their configurations. Furthermore, myoglobin, which undoubtedly is derived from the common 'primitive' hæmoglobin, has diverged considerably from hæmoglobin in its function and structural organization. Therefore, the results obtained by the present analyses of these proteins are quite gratifying and are in good agreement with the present hypothesis. The fact that a moderate number of non-permissible exchanges do occur is quite understandable when one considers the differences between the various molecules.

In a recent discussion of the evolution of cytochrome *c*, Margoliash[13] observed that certain clusters of basic and of hydrophobic residues tended to be preserved intact (an observation in full accord with the present hypothesis), and raised the question of whether this 'conservation is based solely on evolutionary selection for structural features of functional importance' or whether mutations involving basic or hydrophobic residues tend to yield the same type of residues more often than not. This question strikes to the very heart of the problem under consideration, and it might be rephrased as follows: are the observed amino-acid exchanges governed by the present hypothesis, or are they merely the result of the restrictions imposed on mutation by the 'amino-acid code'? At the present time it is still not possible to distinguish conclusively between these two alternatives, but the analyses of the hæmoglobin and myoglobin exchanges, in which multi-step mutations are undoubtedly involved, would appear to support strongly the former alternative.

Besides the theoretical analysis just presented (which will undoubtedly be expanded as the sequences and configurations of additional sets of proteins are examined), it has been possible to approach the hypothesis experimentally. By utilizing the system in which native ribonuclease is 'unfolded' by reduction in urea and is then re-oxidized and 'refolded' to its active configuration, it has been shown that extensive modifications of 'surface' residues (such as lysine, glutamic acid, and aspartic acid) that do not convert polar side chains to hydrophobic ones do not prevent the proper 'refolding' of the unfolded proteins[6,8]. Similar results have been obtained with surface-modified trypsin[7]. On the other hand, the attachment of large aromatic rings to the surface does appear significantly to impair folding[14]. Further experiments of this type, using not only selective modifications of amino-acid side chains but also specific amino-acid substitutions within the polypeptide chain, will allow for a more extensive and definitive experimental test of the hypothesis.

In summary, it seems reasonable at the present time to assert that the available amino-acid sequence data and experimental evidence support the hypothesis that the necessity to preserve the correct tertiary configuration by the proper distribution of polar and hydrophobic residues in protein molecules is an important factor in guiding the evolution of proteins. Therefore, it may be predicted that homologous proteins which violate this principle will be found to differ markedly in their tertiary configurations, although the fact that enzymatic activity and specificity are preserved would suggest that the 'active centre' portions of the molecule may still be relatively intact.

Note added in proof. Fisher[27] has recently suggested that the combination of the chain-length and the ratio of the hydrophobic to polar residues in a protein strongly influences its tertiary and quaternary structures. His conclusions are quite complementary to those reached in the present discussion.

A THEORETICAL MODEL OF γ-GLOBULIN CATABOLISM

By PROF. F. W. R. BRAMBELL, F.R.S., DR. W. A. HEMMINGS and DR. I. G. MORRIS

Agricultural Research Council Unit of Embryology, Department of Zoology, University College of North Wales, Bangor

RECENTLY one of us[1] suggested that certain resemblances between the processes of the passive transmission of immunity from the gut to the circulation in suckling rats and mice and of passive anaphylactic sensitization in guinea pigs warranted the hypothesis that essentially similar cellular mechanisms were involved in both. These two processes are involved in very different and rather special functions, and if they do indeed depend on a similar cellular mechanism the possibility that this may be concerned also with some other process of more general physiological significance arises. Recent new evidence concerning the catabolism of γ-globulin in the mouse[2] and in the rabbit[3] appears to us *prima facie* to lend itself to such interpretation. It is the purpose of this article to suggest a theoretical model of the mechanism of γ-globulin catabolism, consistent with these results and with the assumptions that have been made concerning transmission of immunity in the mouse, rat and rabbit and with anaphylactic sensitization in the guinea pig.

Briefly the case which was made for assuming that a similar receptor mechanism was involved in both sensitization and transmission was as follows. Both processes are concerned with γ-globulins (or antibodies) and both are selective also in that the γ-globulins of some species are effective, whereas those of others are less effective or ineffective. The fragment of the γ-globulin molecule obtained by papainization which contains most of the antigenic sites, known as fragment III or the *F*-piece[4], determines both transmission and sensitization, whereas the other parts, fragments I and II or the *S*-pieces, are ineffective. Sensitization by, or transmission of, a given γ-globulin can be interfered with by γ-globulins of other species, but not by other serum proteins. Again, it is the antigenic part (fragment III) of the molecule, not the other part (fragment I or II), which is responsible for interference. To account for the specificity and selectivity of sensitization and of transmission, workers in both fields have postulated independently the presence of γ-globulin receptors on, or in, the cells and have regarded interference as being due to competition for them.

Transmission involves passage across the gut wall. The protein in solution apparently is taken up by the cells of the intestinal epithelium by pinocytosis, as can be demonstrated microscopically and electron microscopically. Protein so absorbed and not transmitted to the circulation as such appears to be degraded. Thus the receptors, which may be in the walls of the pinocytotic vesicles, appear to function in saving from degradation protein molecules attached to them and later releasing them to be secreted from the other pole of the cell. Sensitization, on the other hand, requires receptors that are accessible to antibodies and soluble antigens and may be on the external surfaces of the cells. It is not necessary to assume that they are in the walls of vesicles within the cells, though there does not appear to be any convincing evidence on which to exclude such a possibility.

Fahey and Robinson[2] find that for *BALB/c* mice the rate of γ-globulin catabolism increased with γ-globulin concentration from a normal half-life of $T\frac{1}{2} = 4{\cdot}1$ days at a normal concentration in the serum of 0·5 g per cent to a minimum half-life of $T\frac{1}{2} = 1{\cdot}8–2{\cdot}0$ days at concentrations of 2·0 g per cent. These mice were used at a size of 25 g body-weight when the average plasma volume was 1·25 ml., and approximately half the total γ-globulin was extravascular. Levels of γ-globulin concentration were raised by hyperimmunization and injection of normal mouse γ-globulin. Comparable reduction of the half-life of γ-globulin was observed in mice with high concentrations of γ-myeloma protein due either to bearing transplanted plasma cell tumours or to injection of the purified myeloma protein, and also in mice that had received injections of normal human γ-globulin or human γ-myeloma protein. Mouse or human β_{2A} myeloma protein, human γ_1-macroglobulin, and human albumin had no effect on the half-life. The *F*-pieces of both normal human γ-globulin and of mouse γ-myeloma protein, obtained by treatment with papain and cysteine, were as effective in shortening the half-life as the whole γ-globulins at comparable molar concentrations, whereas the *S*-pieces did not shorten, and even appeared to slightly lengthen, the half-life.

Our attention was attracted by the resemblance of this phenomenon to passive transmission and to passive sensitization in its specificity, since γ-globulin alone is effective, and the other serum proteins have no effect. Moreover, the effective part of the γ-globulin molecule is the same in all three processes, since the *F*-piece of human γ-globulin corresponds to fragment III of rabbit γ-globulin, and the *S*-pieces to fragments I and II. Such correspondence obviously suggested that a similar basic cellular mechanism might be involved.

The model we suggest to account for these findings is the isolation from the general pool in a special compartment or compartments of a part of the γ-globulin solution, some of the molecules of which become attached to specific receptors on, or in, the cells and are ultimately returned to the circulation, while the remainder are degraded. The essential point is that, of the γ-globulin so isolated, only those molecules which attach to receptors are saved and returned to the circulation. It is suggested that isolation is effected by pinocytosis and that the receptors are intracellular in the walls of the vesicles, but the principle could apply to isolation in a viscus with the receptors on the surface of the cells lining it. Such a mechanism would be consistent with that which we have found it necessary to postulate to account for the passive transmission of immunity and appears to us applicable at least to much that is known concerning passive anaphylactic sensitization. The fractional rate of γ-globulin catabolism, *F*, is the amount catabolized in unit time divided by the total amount in the system. If *V* is the total γ-globulin space, and *c* is the concentration, then the total amount in the system is *Vc*. The proportion catabolized will be the proportion isolated less the proportion saved by the receptors. If *a* is the proportion of the total γ-globulin solution isolated per day and *b* is the minimum concentration of γ-globulin that will saturate the receptors, then:

$$F = \frac{Vac - Vab}{Vc} \qquad (1)$$

Since the half-life, $T\frac{1}{2}$, is related to the fractional rate of catabolism, as:

$$T\tfrac{1}{2} = \frac{\log_e 2}{F} \qquad (2)$$

then by substitution:

$$T\tfrac{1}{2} = \frac{c \log_e 2}{a(c-b)} \qquad (3)$$

Similarly, the total amount of γ-globulin catabolized per day, *G*, will be:

$$G = Va(c-b) \qquad (4)$$

Fahey and Robinson[2] provide results for the serum γ-globulin concentrations and half-lives in normal and immunized mice of the *BALB/c* strain which are reproduced in Table 1. These authors provide further results in the form of a graph of the γ-globulin concentrations and half-lives in mice with various kinds of plasma cell tumours, or injected with large doses of mouse of human myeloma protein, or normal human γ-globulin, or human serum albumin. We have extracted these results from their graph for normal mice and for those injected with human serum albumin, which we consider strictly relevant, and reproduce them, together with those for the immunized mice, in Fig. 1, plotting half-life against γ-globulin concentration. On the simplest assumption that the amount isolated is constant irrespective of γ-globulin concentration, the values of the constants *a* and *b* can be estimated graphically, since when $T\frac{1}{2} = \infty$, $c = b$, and when $c = \infty$, $a = \log_e 2/T\frac{1}{2}$. The values determined in this way were found to be $a = 0{\cdot}34$ and $b = 2{\cdot}5$. Solving equation (3) with these values gives the curve shown in Fig. 1 with a theoretical minimum half-life of 2·05 days. The expected half-life for each γ-globulin concentration, derived from this curve, is given in Table 1 for comparison with the observed half-life. It can be seen that the curve is consistent with the data, allowing for experimental errors inseparable from determinations of γ-globulin concentrations in small samples.

Table 1. CONCENTRATIONS AND HALF-LIVES OF γ-GLOBULIN IN NORMAL AND IMMUNIZED MICE (DATA FROM FAHEY AND ROBINSON[2])

Concentration mg/ml.	Half-life (days) Observed	Expected
5·0	4·0–4·3	4·0
7·2	3·5–3·6	3·1
6·8	3·3	3·2
15·6	2·5–2·7	2·4
28·0	1·9–2·2	2·2

It was desired to test whether equation (3) was equally applicable to other species. Unfortunately few reliable data covering the necessary range of γ-globulin concentrations are available in the literature. Recently Anderson and Bjorneboe[3] have provided determinations of both half-lives and concentrations of γ-globulin in seven rabbits before and during hyperimmunization which are appropriate. These are shown in Fig. 2, together with the curve derived from equation (3), using the values $a = 0{\cdot}21$ and $b = 4{\cdot}74$. The observed values, together with the expected values of the half-life for each γ-globulin concentration

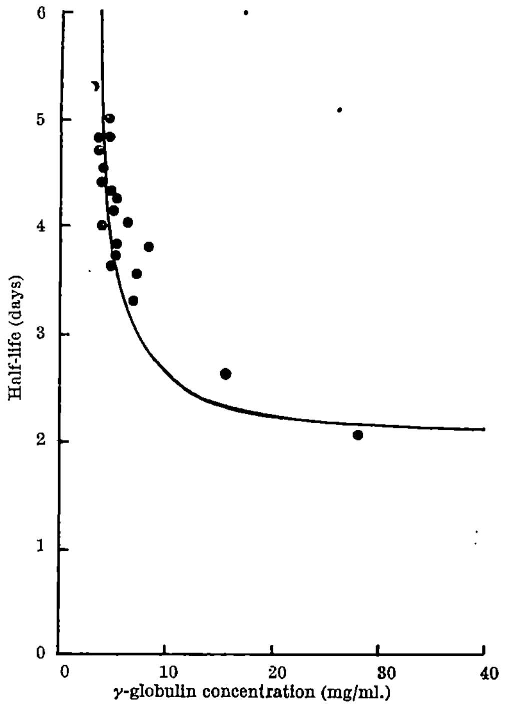

Fig. 1. Relation of half-life to serum concentration of γ-globulin in mice; $a = 0{\cdot}34$, $b = 2{\cdot}5$. Data extracted from Fahey and Robinson[2]

derived from this curve, are given in Table 2. It can be seen by inspection that the fit is reasonably good.

Table 2. CONCENTRATIONS AND HALF-LIVES OF γ-GLOBULIN IN RABBITS BEFORE AND DURING HYPERIMMUNIZATION
(Data from Andersen and Bjorneboe[3])

Before hyperimmunization			During hyperimmunization		
Concentration mg/ml.	Half-life (days) Observed	Half-life (days) Expected	Concentration mg/ml.	Half-life (days) Observed	Half-life (days) Expected
11·5	4·2	5·6	52·9	3·3	3·6
16·2	4·8	4·7	53·2	3·2	3·6
10·6	5·7	6·0	71·4	3·4	3·5
11·5	4·9	5·6	109·1	3·7	3·4
12·5	5·6	5·3	97·2	3·8	3·5
9·7	6·1	6·5	83·3	3·2	3·5
12·9	7·3	5·2	79·7	3·8	3·5
Mean: 12·1	5·5	5·6	78·1	3·5	3·5

The concepts from which equation (3) is derived have been drawn from the phenomenon of passive transmission of immunity, yet the curves defined by this equation fit remarkably well the data of the relation of half-life to concentration of γ-globulin. These results refer to two unrelated species and were obtained by two independent groups of workers. This hypothesis of the mechanism of γ-globulin catabolism is attractive because of its relative simplicity. Both the fixation of γ-globulin to cellular receptors and pinocytosis are well-recognized concepts. The hypothesis is novel in relation to γ-globulin catabolism in so far as it involves both these mechanisms and postulates that the receptors are in the walls of the vesicles and that the molecules which attach to them are saved from degradation and returned to the circulation. Such a mechanism could provide a means of automatic monitoring of the circulating γ-globulin for defects, since any distortion of a molecule that prevented its attachment to a receptor would result in its degradation. It brings into line the special processes of passive transmission of immunity and of anaphylactic sensitization with the general process of γ-globulin catabolism. As a working hypothesis it has the merit of lending itself to experimental verification.

Neither the concentration of albumin nor of the other serum globulin affects the half-life of γ-globulin, presumably because their molecules are unacceptable to the γ-globulin receptors. Hence, unless separate specific receptors for these serum proteins are present in the walls of the pinocytotic vesicles also, of which there is no evidence at present, then all these molecules taken up with the γ-globulin by pinocytosis would be expected to be degraded. On this assumption the half-life of these serum proteins should not exceed the minimum half-life of γ-globulin. It is suggestive that Fahey and Robinson[2] find the half-life of serum albumin in their mice to be 2·1 days. Since this is the theoretical minimum half-life of γ-globulin, it leaves no margin for the catabolism of albumin by any other channel.

The problem of where in the body γ-globulin is catabolized is not involved in this hypothesis. The gut is an attractive possibility, however. There is evidence that substantial quantities of γ-globulin and other serum proteins are secreted into the small intestine. Recently Andersen, Glenert and Wallevik[5] found that in dogs, in which the half-life of γ-globulin had been measured previously, 38 per cent of the total γ-globulin catabolized per day was accounted for by intestinal clearance. They used iodine-131-labelled homologous γ-globulin injected intravenously, and measured the appearance of the labelled protein in isolated washed-out intestinal loops. They assumed that any γ-globulin reaching the lumen of the small intestine is degraded there. If such quantities of γ-globulin do in fact reach the intestinal lumen in the normal animal and are there degraded *in toto*, it would be incompatible with the hypothesis of γ-globulin catabolism outlined above. Andersen *et al.*, however, provide no crucial evidence of such degradation and in fact their results provide some evidence against it. They found that about 50 per cent of the activity in the fluid aspirated from the loop was not protein bound. However, when ^{131}I-γ-globulin solution was injected into the loops in dogs which had not had it intravenously, only 1·2 per cent of the activity was non-protein bound after the same interval. This suggests that the breakdown products in the intestinal lumen of the intravenously injected dogs were not the result of degradation in the lumen but may have reached it from elsewhere. The results are consistent with the assumption that the γ-globulin exuded into the small intestine is not degraded

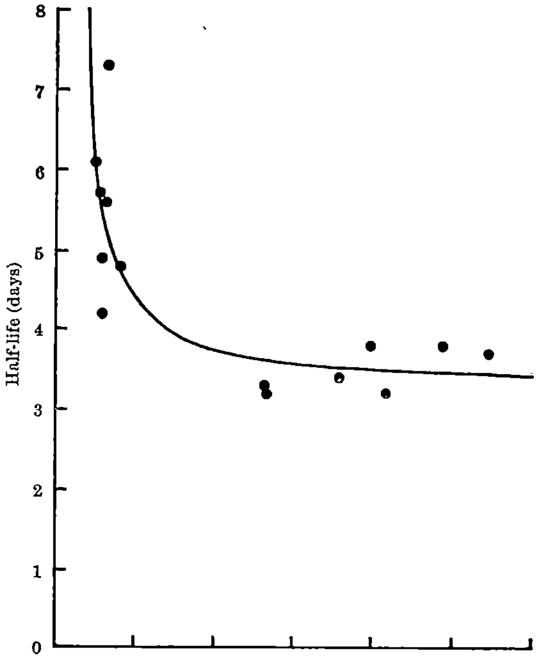

Fig. 2. Relation of half-life to serum concentration of γ-globulin in rabbits before and after hyperimmunization; $a = 0{\cdot}21$, $b = 4{\cdot}74$. Data extracted from Andersen and Bjorneboe[3]

in the lumen but may be reabsorbed by a similar method to that of the suckling rat or mouse, such molecules as are attached to the receptors being saved and returned to the circulation and such as are not so attached being degraded. Diffusion of these degradation products into the lumen could account for the appearance of non-protein bound iodine-131 there. This is equivalent to suggesting that the change in the gut that results in termination of transmission of immunity at some time after birth is due to the onset of gastric and duodenal function and that the small intestine is still capable of transmission provided that the γ-globulin reaches it without having traversed more anterior regions of the gut. The small intestine of the adult could be the site of at least a significant fraction of γ-globulin catabolism by precisely such a mechanism as is postulated by our model.

We thank Prof. C. L. Oakley for his advice.

SYRIAN HAMSTER FIBROBLAST CELL LINE *BHK*21 AND ITS DERIVATIVES

By Prof. MICHAEL STOKER and Dr. IAN MACPHERSON
Medical Research Council Experimental Virus Research Unit, Institute of Virology, University of Glasgow

THE *BHK*21 line of diploid hamster fibroblasts is used widely for research on viruses and on neoplastic transformation. The purpose of this article is to describe the origin of the cells, to list viruses to which they are susceptible, and to summarize the main characteristics of some variants of the cells.

Origin. *BHK*21 cells arose from cultures of kidneys from 1-day-old Syrian hamsters[1]. Such cultures are initially mixtures of fibroblasts and epithelial cells in which fibroblasts soon predominate. They can usually be propagated for about 8 weeks before growth slows and eventually ceases, but in one series of cultures rapidly growing cells were found after 65 days in culture.

The primary cultures from which these cells were derived were prepared in March 1961 from the kidneys of 5 1-day-old hamsters from litter No. 21. After 30 days and three subcultures a sample was stored at −70° in glycerol for 8 days before continuous culture was continued. Tests were carried out for sensitivity to polyoma virus transformation on the 24th, 31st, 36th and 48th day of continuous cultivation (excluding the storage period). These involved plating the cells, and from the earliest test on the 24th day large fibroblastic colonies were noted. Nevertheless the growth rate and cloning efficiency of the cells remained low and 10^5 cells was insufficient to form a confluent monolayer in a 60-mm Petri dish in one week. Between the 31st and 41st day kanamycin sulphate ('Kannasyn', Bayer Products Co., Surbiton upon Thames) was added to the medium because contaminants were found in a few cultures.

On the 41st day some cultures were exposed for 2 days to the medium which had been used for baby hamster kidney cells from another litter, in an unsuccessful attempt to transfer resistance to polyoma transformation[2].

Finally, after 65 days of propagation a sudden increase in growth rate was noticed, with a large increase in yield of cells from each culture. This was confirmed on the 67th day, when a sample of the cells was tested for polyoma transformation and it was found that 10^5 cells formed a thick confluent growth after one week in a 60-mm Petri dish.

The cells which are the source of all *BHK*21 cells are from those cultures which had been exposed to the exchange of medium, but a control culture not so treated was later found to be growing rapidly, so the medium exchange was probably irrelevant. It should be noted that the rapidly growing cells had not been knowingly exposed to polyoma virus during their propagation, and derivatives have since been shown to lack the polyoma specific cell antigen[3,4].

Nineteen days after the change in growth rate was first observed, 8 clones were grown from single cells in small drops of medium under mineral oil. One of these, designated *BHK*21/13 (or *C*13), has been extensively examined and is the source of most cells distributed from this laboratory.

A sample of the original uncloned *BHK*21 cells was frozen at −70° two days after the rapid growth was first observed. Clone *BHK*21/13 cells were stored after about 24 cell generations, that is, when the population reached 10^8 cells. Further stocks of the clone for general use have been frozen after a total of about 30 generations since cloning.

Characteristics of BHK21 cells. *BHK*21 cells are elongated and grow in parallel orientation, like fibroblasts. In logarithmic growth they have a mean doubling time of 12 h (ref. 5) when grown in medium containing 10 per cent autoclaved tryptose phosphate broth (Difco), and 10 per cent unheated calf serum, in Eagle's medium with twice the usual concentration of amino-acids and vitamins.

Growth is maintained even after the cell sheet is confluent, so that the final saturation density of the cells is approximately 10^6 cells per cm^2 of glass, some ten times the saturation density of freshly isolated cells.

When dilute suspensions of monodispersed cells are cultured, on average 16 per cent grow to form colonies. In the presence of X-irradiated feeder cells this figure is raised to at least 50 per cent.

Cells stored in medium containing glycerol or dimethyl sulphoxide can be resuscitated with high viability after long periods at −70° or −196° C.

The karyotype of *BHK*21 cells is that of diploid male Syrian hamster cells[5] and has remained so in *BHK*21/13 for at least 450 generations. At this stage the distribution was: 43 chromosomes—4 cells; 44 chromosomes—55 cells; 46 chromosomes—2 cells. In a larger sample 0·4 per cent were in the tetraploid region.

On implantation of large numbers of *BHK*21 cells in unconditioned adult hamsters progressively growing fibrosarcomas develop after a latent period of several months. One million cells produce tumours in 50 per cent of animals in 3 months when implanted intracerebrally, and in 13 per cent of animals in 8 months when implanted subcutaneously[6]. This low transplantability contrasts strongly with that of the highly malignant variants described here.

Sensitivity of BHK21 cells to viruses. The following viruses are known to multiply in *BHK*21 or *BHK*21/13 cells. *Pox viruses*: Vaccinia. *Herpes viruses*[7]: Herpes simplex, pseudorabies, bovine rhinotracheitis, equine abortion. *Myxoviruses*[8]: Influenza NWS, NM, fowl plague, NDV, mumps, Sendai. *Arboviruses*[9–12]: Groups *A*, *B*, *C*, Bunyanwera, Guama, Simbu, Triniti, VSV, Anopheles *A* and *B* and California complex. *Encephalomyocarditis virus*. *Rabies virus*[13] (several strains). *Foot-and-mouth virus*[14] (several strains). *Vesicular stomatitis virus*[15].

In addition non-neurotropic strains of influenza virus undergo an incomplete cycle[8]. Polyoma virus induces transformation, but infective virus is not produced in detectable amount[16].

Polioviruses Types 1, 2 and 3, and several strains of common cold virus[17], have been tested and not found to multiply.

No difference has yet been found in the viral sensitivity of *BHK*21 cells after polyoma virus transformation.

'Spontaneous' variants of BHK21 cells. When uncloned *BHK*21 or *BHK*21/13 cells have been propagated for long periods or deliberately exposed to selective conditions, the following variants have been isolated. These are not due to polyoma infection and are presumably due to mutation, or to transformation, possibly by unknown viruses.

(*a*) *High transplantability.* Cell lines with increased transplantability have been isolated in several laboratories[6,18–20]. These range from highly malignant (for example, *BHK*21/*Is*3), with a minimum tumour-producing dose of less than ten cells inoculated intracerebrally, to intermediate types (for example, *BHK*21/13/150), requiring approximately one hundred cells. In transplantability these variants resemble cells transformed by polyoma virus, but, as demonstrated by Defendi *et al.*[18], this property is not correlated with random orientation, nor with the possession of the polyoma cell antigen. Nevertheless these cell lines appear to us to have less oriented growth pattern than the original *BHK*21 cells.

(*b*) *Growth in suspension.* A variant capable of growth in suspension has been described by Capstick *et al.*[21].

(*c*) *Growth in agar.* Standard *BHK*21 cells will not grow in agar, but Montagnier has isolated a variant which will form colonies with an average efficiency of 15 per cent when embedded in agar[22].

Polyoma transformed variants of BHK21 cells: (*a*) *Standard.* Neoplastic transformation of *BHK*21 cells can be produced rapidly by exposure to polyoma virus. After transformation the cells lose all trace of infective virus. Compared to the original cells the polyoma transformed cells are characterized by high transplantability in hamsters (minimum tumour-producing dose of 60 cells intracerebrally), random orientation in culture, increased glycolytic capacity, and a virus specific cell antigen. One transformed clone (*BHK*21/13/*Py*6) has been compared in detail with *BHK*21/13 cells from which it was derived[5,6].

(*b*) *Tetraploid.* The karyotype of the standard freshly transformed cell is diploid, but aneuploid cells rapidly appear and the proportion of tetraploid cells increases on propagation. A few clones, however, contained tetraploid cells exclusively when first examined soon after transformation. In these cells tetraploidy persisted on further propagation[5,23].

(*c*) *Colonial morphology.* A variant, termed Colony Type 2, may be observed in freshly transformed clones of less than 10^3 cells infected with cloned virus stock. Type 2 is characterized by a greatly increased proportion of rounded but viable cells which lie on top of the colony. This feature is maintained on propagation but soon reverts to the standard (Type 1) type of colony.

(*d*) *Increase in electrophoretic mobility.* The electrophoretic mobility of freshly transformed clones may either be unchanged or increased[24]. After continuous propagation, however, the mobility becomes heterogeneous[25].

(*e*) *Growth as ascites cell.* A particularly interesting variant of *BHK*21/*Py*6 has been obtained by Sanders and Burford[26] by adaptation to the hamster peritoneal cavity. These ascites cells, when cultured directly, will grow in agar with cloning efficiency of about 30 per cent. After passage in agar this increases to nearly 100 per cent.

(*f*) *Growth in agar.* Some freshly transformed clones will give rise to colonies in agar without adaptation as an ascites cell[27]. These include polyoma transformed derivatives of the agar growing variant[22] (see foregoing). (It is now known that the ability to form colonies in agar is rapidly acquired after polyoma transformation[37].)

(*g*) *Biochemical markers.* Spontaneous variants (not shown in Table 1) with increased resistance to purine analogues, or antibiotics, such as puromycin, have been isolated from *BHK*21/*PyY* cells and also from untransformed *BHK*21 cells by Subak-Sharpe[28].

Table 1. CHARACTERISTICS OF SOME VARIANTS OF *BHK*21 CELLS

Main characteristic		Full designation of representative clones or lines	Ref.
Original	Original uncloned *BHK*21	*BHK*21	1
	Clones of *BHK*21	*BHK*/13, etc. (or *C*13)	
Spontaneous variants	High transplantability	e.g., (*a*) *BHK*21/13/798 (*b*) *BHK*21/*Is*3 (*c*) *BHK*21/13/150	(*a*) 18 (*b*) 19 (*c*) 6
	Growth in suspension	*BHK*21/13/*Susp.*	21
	Growth in agar	*BHK*21/13/*Ag*	22
Polyoma virus transformed	Standard	e.g., *BHK*21/13/*Py*6 (previously *TC*6) *BHK*21/13/*PyY*, etc.	5 23
	Tetraploid	e.g., *BHK*21/*PyC* *BHK*21/13/*PyZ*	5 23
	Rounded (Type 2) morphology	e.g., *BHK*21/13/*PyM*	
	Increase in electrophoretic mobility	e.g., *BHK*21/13/*PyP*	25
	Ascites adapted (also grows in agar)	*BHK*21/13/*Py*6/*As*	26
	Growth in agar	*BHK*21/13/*Py*/*Ag*	27 22

A list of these variants and their sources and designations is given in Table 1. For regular use the designations may be suitably abbreviated by the use of the last letter or figures. It should be noted that the standard clone *BHK*21/13 has frequently been referred to as *C*13. Polyoma transformed clones are now designated *Py* (instead of *T* as previously) because of the possibility of transformation by other viruses.

Comparison with other cell lines. *BHK*21 cells differ from freshly isolated fibroblastic cells in their high cloning efficiency, and their rapid growth for an apparently indefinite period. They thus come into the category of a cell line rather than a cell strain[29]. On the other hand, they resemble freshly isolated cells in being diploid, a character they have retained through many generations and in which they differ from other continuous lines of cells. Though no regular abnormality has been found in the chromosome number of *BHK*21 cells, it is possible that, like some Chinese hamster cell lines[30], these cells are quasi-diploid.

It seems likely that *BHK*21 cells are derived from a variant arising after many weeks in culture. If it had been present in the original kidneys or in the early cultures from them, the high growth rate should have allowed a rapid emergence. However, the presence of unusually large fibroblastic colonies noted after 24 days in culture, and 41 days before the *BHK*21 cells were observed, may mean that two or more steps were involved. The variant is probably rare and no similar cells have been obtained from 47 separate batches of baby hamster kidney cells in our laboratory. The rapid decline of Syrian hamster cells and the dearth of variants have also been the experience of other workers[31].

It is of interest to note that the frequency of emergence of cell lines from normal (as opposed to tumour) tissue seems to be a function of the species of origin. Human fibroblasts survive in the euploid condition for a comparatively long time, but continuous cell lines rarely arise[29]. Rat cells may behave similarly[32]. On the other hand, mouse cells rapidly decline in growth rate when cultured and frequently give rise to aneuploid variants capable of indefinite growth[33,34]. A third class exists in which continuous cell lines may appear but are not markedly aneuploid. The chromosome number may not be changed or only changed by one or two. Chinese hamster[35] and perhaps pig cells[36] belong to this class, and it is possible that Syrian hamster cells should be included as well.

Though highly malignant variants arise in the absence of polyoma virus transformation it is likely that the original *BHK*21 cells are not malignant. The slow-growing tumours which can arise from large cell inocula even after cloning may be due to a few malignant variants which were already present by the time the clone was tested, or which arose during the long latent period following implantation. These malignant cells have little selective advantage under the growth conditions used in our laboratory, but in other laboratories they may rapidly replace the original cells.

Normality is only a relative term when applied to cells in culture, and whatever the status of *BHK*21 cells in relationship to the kidney cells of the baby hamster or to freshly cultured fibroblasts they should prove useful in biological research. Viruses, such as those of foot-and-mouth disease and rabies, which grow poorly in other continuous lines, multiply well in *BHK*21 cells, and the cells are sensitive to the transforming action of polyoma virus. Finally, the rapid growth and high cloning efficiency of *BKH*21 cells combined with a low chromosome number may make them especially suitable for physiological and genetic studies.

GLOMERULONEPHRITIS AND LATE ONSET DISEASE OF MICE FOLLOWING NEONATAL VIRUS INFECTION

By JOHN HOTCHIN and DORIS N. COLLINS

Division of Laboratories and Research, New York State Department of Health and Institute of Preventive Medicine,
Albany Medical College, New York

NEONATAL inoculation of mice with lymphocytic choriomeningitis (LCM) virus has been shown[1] to cause a persistent infection of the animal with high virus titres lasting for many months after inoculation. During this period the mice remain perfectly well[2] and free from signs of disease, except for a brief temporary period of runting in some mouse strains; the blood causes severe hepatitis and death with convulsions if inoculated intracerebrally or intraperitoneally into an uninfected litter mate or other mouse more than 4 days old[3]. This harmless LCM virus infection has been called persistent tolerant infection (PTI)[4] and appears to parallel the carriage of human serum hepatitis virus in man. Initially it was believed that LCM–PTI mice were entirely comparable clinically to uninfected or LCM-immune controls throughout the normal life span of the mouse. However, comparison of PTI and control mice[5] showed that PTI mice weighed a few grams less than uninoculated controls or mice of the same age which had received an injection of the virus by the subcutaneous route at approximately 1 month of age. (The latter are actively immune to the virus if challenged, and contain circulating antibody against LCM but no circulating virus.) In addition, the onset of a chronic late-onset disease was noticed with the occurrence of renal lesions in some respects similar to human systemic lupus erythematosus (SLE)[5-7]. This article describes the results of a preliminary investigation of this new late-onset disease.

Mice of both Albany and Swiss strains[4] were used with the M/B_7L_{11} (ref. 8) strain of LCM virus. A large number of PTI mice were obtained from experiments concerning the effects of various factors on the induction of immunological tolerance to LCM virus; some of these have been reported elsewhere[8]. In addition, 4 large groups of mice—PTI, LCM-immune, mice inoculated with normal tissue, and uninoculated mice—were set up to follow the course of tolerant infection in later life. All mice were checked at weekly intervals for onset of clinical signs of late

Table 1. INCIDENCE OF CLINICAL LATE DISEASE AND RENAL LESIONS IN MICE

Mouse category	Incidence* of clinical late disease	Percentage of clinical late disease	Incidence of histological kidney lesions†	Percentage of kidney lesions
Albany PTI	92/109	85·0	17/50	34
Albany control	2/121	1·6	0/42	0
Swiss PTI	76/167	46·0	19/118	16
Swiss control	2/136	1·5	0/7	0
Total mice	533		Total kidney sections 217	

* The second figure denotes the number of mice in the group.

† The second figure denotes the number of mice on which renal histological examination was performed.

disease; if definite signs were noted, mice were checked daily and killed when severely ill or when death appeared imminent.

The PTI mice remained well for approximately 7–10 months, at which time they began to show the characteristic disease picture of 'late disease'. Such a mouse exhibiting the ruffled and sparse fur, hunched posture, and moth-eaten appearance is shown in Fig. 1 with normal controls for comparison; the incidence of clinical late disease and renal lesions is shown in Table 1. Of the mice examined, 85 per cent of the Albany strain showed clinical evidence of late disease at some point after their 7th month of life, whereas the corresponding figure for Swiss mice was only 46 per cent. Some of the mice in both these groups, regardless of whether or not they showed clinical late disease, were sampled at ages between 7 and 18 months for histological examination of their organs; 34 per cent of the Albany and 16 per cent of the Swiss mice showed specific renal lesions; this trend conforms with the lower tendency of the Swiss mice to exhibit clinical signs of late disease. Occasional mice showed the renal lesion but not clinical late disease. The histological examination of approximately 168 PTI and 49 control mice aged between 5 and 32 months revealed the following.

The gross appearance of the kidneys was somewhat paler and slightly larger than normal. The glomeruli showed a diffuse involvement of the capillary tufts with hyaline thickening of the basement membrane of the capillary loops, and occasionally Bowman's capsule showed thickening, splitting, or reduplication (Fig. 2). There was accumulation or deposition of material on the intraluminal surface of the capillary basement membrane which resulted in partial or complete obliteration of the lumen and in areas simulated a 'wire loop' appearance (Fig. 3). A thin layer of material presenting a laminated structure with ridges perpendicular to the basement membrane was noted on the extra-luminal surface of the capillary tufts. No lesions of this type or significant clinical evidence of late disease were found in any of the control mice. No differences have become apparent so far between any of the control sub-groups.

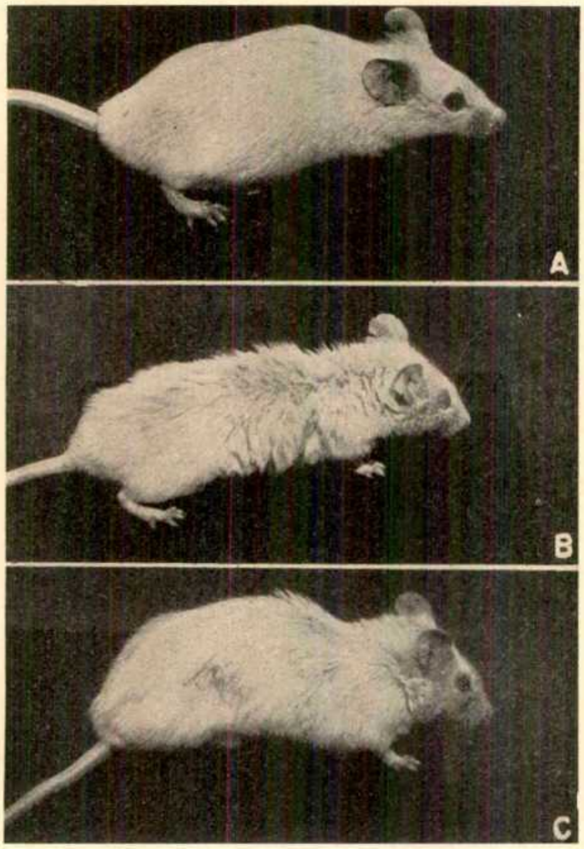

Fig. 1. *A*, control mouse inoculated at birth with normal mouse brain suspension, showing normal appearance, photographed at 14 months of age, weight 38·4 g; *B*, mouse inoculated with LCM virus at birth showing moderately severe late disease, photographed at 13 months of age, weight 28 g; *C*, control uninoculated mouse, aged 30 months, weight 29·5 g. This animal is at the extreme limit of old age, the signs of which are clinically quite distinct from those of late disease

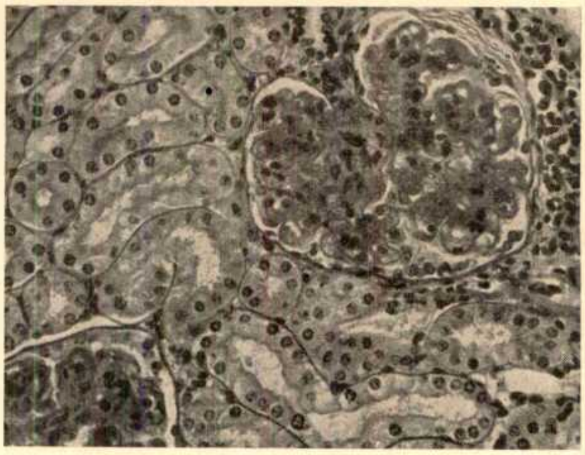

Fig. 2. Thickened basement membrane, splitting or reduplication of Bowman's capsule, and accumulation of mononuclear cells. Periodic acid-Schiff stain. (× *c*. 115)

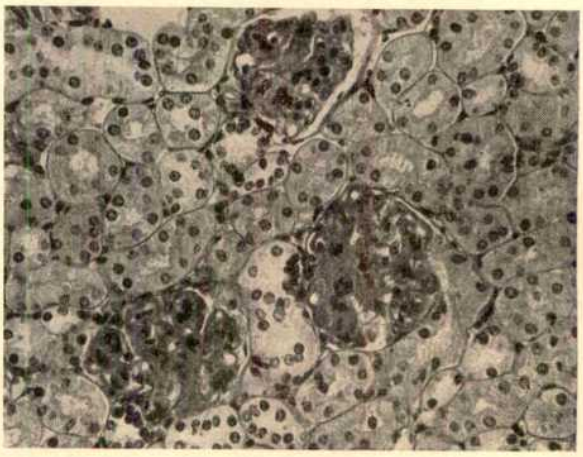

Fig. 3. Diffuse hyaline thickening of basement membrane, accumulation of material on capillary basement membrane with partial to complete obliteration of lumen. Periodic acid-Schiff stain. (× *c*. 115)

In affected kidneys, the glomeruli were uniformly involved throughout the cortices. The tubules frequently contained fine droplets and laminated concretions in the epithelial cells, but casts were rarely present at this stage of glomerular involvement. In severely damaged kidneys, the glomeruli exhibited hypercellularity, adhesions of the glomerular tufts, and occasionally epithelial crescents (Fig. 4). The tubules were dilated and contained homogenous acidophilic casts. An almost constant finding was a perivascular accumulation of lymphocytes and plasma cells about arcuate and intralobular arteries. The glomerular deposits stained with periodic acid-Schiff reagent showed an intense positive reaction; congo red and alcian blue stains were negative for amyloid. No birefringence or dichromism was noted on congo-red stained sections when examined by polarized light. Fluorochrome staining with thioflavin T exhibited no fluorescence of the glomerular deposits[9]. Glomerular amyloidosis was present in a large number of PTI and control mice in the slightly older age group; this appeared to be most marked in the Swiss strain and in the PTI mice. The deposition of amyloid

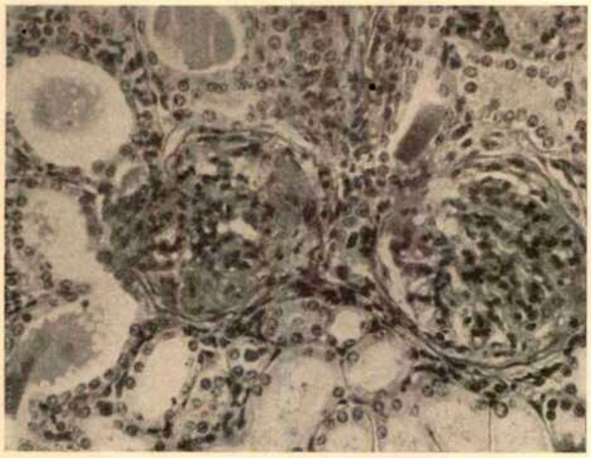

Fig. 4. Hypercellular glomeruli, adhesions and epithelial crescent. The tubules are dilated and contain casts. (× *c*. 115)

in these mice was generally confined to the glomeruli and did not involve the medulla and papillæ of the kidney, neither was it identified extra-renally.

A few of the renal sections showing typical glomerular lesions were stained by the fluorescent antibody technique using an antimouse γ-globulin fluorescent conjugate. Marked fluorescent staining of the glomerular deposit occurred; however, similar staining also occurred in sections showing severe amyloidosis, from mice uninfected with LCM virus.

The finding of severe clinical disease and renal lesions as a late sequel to neonatal virus infection raises the question of the nature of the pathogenic mechanism of this disease and its relation to acute LCM pathogenesis. There is considerable evidence[4] that the acute phase of LCM disease represents the outer manifestations of an immunological conflict occurring between the replicating viral antigen and the host's immune mechanism; however, the acute infection of adult mice with our strain of LCM shows meningoencephalitis and hepatitis, without noticeable kidney involvement. It has been suggested[5] that the host's response is essentially the same as the homograft response and constitutes a delayed hypersensitivity mechanism designed to eliminate the virus-infected tissue of the animal. This in turn suggests that the late disease of PTI mice may occur as a result of the gradual waning of immunological tolerance formerly exhibited by the mouse towards an otherwise harmless virus infection, thus constituting an example of virus-induced auto-immune disease. In this light, the late disease syndrome might be considered as a possible auto-immune reaction of the host immune mechanism towards previously tolerated tissue components. This view is compatible with the lesions found, and the fluorescent staining results, but has not been confirmed by serological or other evidence of SLE: thus, significant evidence for this view must be considered lacking at present. Alternatively the disease may arise from a very slow type of cytopathic effect on certain target tissues such as those found in the kidney. It must also be remembered that the mouse contains other latent viruses and micro-organisms which as contaminants of the LCM virus-infected tissue suspension used for inoculation could conceivably be responsible for the late lesions, although all tests for such agents have been negative.

The nature and significance of the renal lesions cannot at present be finally assessed. The glomerular changes, while exhibiting some features of lupus nephritis, rarely showed fibrinoid necrosis, and hæmatoxylin bodies were never demonstrated. That they might represent precocious changes related to senile amyloidosis as described by Dunn[10] and also by Thung[11] was not borne out in the failure to obtain positive results for amyloid using classical amyloid stains[9]. The presence of senile amyloid which was found in the older PTI mice might be expected to occur at about 18 months of age although it may vary with the mouse strain used. It is hoped to answer the question of whether the deposition of periodic acid-Schiff-positive material is a precursor of amyloidosis by a more extensive quantitative histological investigation which has been initiated. Helyer and Howie[12] have described renal lesions in an inbred strain of *NZB* mice which are remarkably similar to those seen in the PTI mice; their cross-bred strain showed the hunched posture, cachexia, and alopecia similar to the PTI mice, but in addition their cross-bred strain developed hæmolytic anæmia and jaundice, and SLE cells were demonstrated; these features were believed to be indicative of an auto-immune process. However, the possibility exists that a persistent tolerant virus infection could be responsible for the effects described by Helyer and Howie, and this does not appear to have been ruled out by their results.

Guttman and Kohn[13] described an intercapillary glomerulosclerosis in ageing mice, and a spontaneous hyaline form of degeneration has been noted in ageing mice of the *RF* strain by Gude and Upton[14]; their morphologic descriptions and photomicrographs are similar to but not identical with those in our investigation of younger PTI mice.

The very late onset of the disease in PTI mice is reminiscent of the gradual onset of scrapie infection in sheep several years after inoculation, and also in mice, which has been shown to occur after several months[15,16]; it would therefore appear to constitute an example of 'slow' virus infections as defined by Gajdusek[17]. The fact that scrapie was for a long time considered to be a non-infectious hereditary disease raises the question of the role of viruses in other 'genetic' conditions, in terms of the carriage of LCM through generations of mice in a closed colony[18], and as already mentioned, in the congenital disease described by Helyer and Howie. If similar mechanisms of chronic virus disease occur in man, serum hepatitis virus carriers should ultimately succumb to some form of chronic organic disease, possibly of the kidney or liver, in later life; a somewhat similar mechanism was proposed by Himsworth[19] to explain the progressive sequence of subacute hepatitis. The role of relatively 'harmless' viruses in the initiation of human late-onset disease has long been suspected, but proof of this remains elusive. The occurrence of late disease in LCM–PTI mice constitutes an example of an infective wasting disease, with an incubation period greater than half the normal expected life span of the host. This evidence strengthens the concept that other diseases of later life may, like some types of cancer, owe their origin, not to faulty genetics, but to a slowly acting but insidiously destructive virus.

EVIDENCE FOR REPAIR OF ULTRA-VIOLET DAMAGED DEOXYRIBONUCLEIC ACID IN CULTURED MAMMALIAN CELLS

By DR. RONALD E. RASMUSSEN and DR. ROBERT B. PAINTER

Exobiology Division, National Aeronautics and Space Administration,
Ames Research Center, Moffett Field, California

AS an extension of our previous work on ionizing radiation effects on nucleic acid metabolism in cultured mammalian cells[1], we have initiated a similar investigation of the effects of ultra-violet light. Results accumulated so far strongly suggest that an active ultra-violet repair mechanism exists in mammalian cells, and is especially evident in cells that have incorporated brom-uracil deoxyriboside (BUdR) into their DNA.

Setlow and Carrier[2] and Boyce and Howard-Flanders[3] have recently reported evidence indicating that dark repair of ultra-violet light damaged DNA in *Escherichia coli* occurs by excision of damaged areas containing thymine dimers. Presumably the next step is the replacement of the nucleotides which have been removed, and Pettijohn and Hanawalt[4] have reported that a "non-conservative replication" of DNA does occur following irradiation of *E. coli*.

Repair and/or recovery mechanisms in mammalian cells are operative following irradiation with ionizing radiation[5], but the molecular basis of this phenomenon is, as yet, unknown. Little work has been done with ultra-violet irradiation of mammalian cells, *in vitro*, although Lee and Puck[6] determined the effect of ultra-violet on the survival of HeLa *S*3 cells and Bloom and Leider[7] have shown that microspot irradiation with ultra-violet causes loss of ultra-violet-absorbing materials from the chromosomes of newt heart cells in culture. Humphrey *et al.*[8] have determined the relative sensitivity to ultra-violet of the different phases in the cell cycle in Chinese hamster cells.

HeLa *S*3 cells and the Chinese hamster line *DFAF*-33, routinely maintained in Eagle's medium, were grown as monolayers in special flasks made of 'Vycor' (Corning No. 7910) or Leighton tubes with 'Vycor' windows (Corning No. 7900) 2 mm thick with a transmission of about 70 per cent at 2537 Å. Two or three days prior to irradiation, the medium of half of the cultures was replaced with one containing $1\cdot6 \times 10^{-5}$ M 5-BUdR (5 µg/ml.) (International Chemical and Nuclear Corp.) and of the other half with one containing $1\cdot6 \times 10^{-5}$ M thymidine (TdR) (4 µg/ml.) (Nutritional Biochemical Corp.). Simon[9] has shown that HeLa cells incorporate BUdR into their DNA when it is included in the growth medium; radioisotopic investigations with ^{14}C-BUdR have shown that, under our conditions, at least 3·5 per cent of the thymidine moieties of DNA are replaced by bromuracil (BU). Immediately before irradiation, the cells were washed twice with bicarbonate buffered normal saline, the flasks flushed with 5 per cent carbon dioxide–95 per cent air, and irradiated, through the surface to which cells were attached, with 2537 Å light from a low-pressure mercury arc ('Mineralight'), at a dose rate of about 5 ergs/mm^2/sec at the surface of the flasks. In the case of the Leighton tubes, the glass cover-slips, which had been placed in the tubes before inoculation and on which the cells had grown, were turned over prior to the irradiation so that the cells were irradiated directly through the 'Vycor' window. Following irradiation, the saline solution was removed and replaced with Eagle's medium containing the labelled compound(s), the flasks flushed again with 5 per cent carbon dioxide–95 per cent air, and incubated at 37° for periods up to 2 h.

Incorporation of nucleic acid precursors was measured with several isotopic compounds. Tritiated thymidine (H^{3}TdR) at a specific activity of 6·7 c./mM was used at a concentration of 0·036 µg/ml.; ^{14}C-labelled thymidine (^{14}CTdR) (30 mc./mM) at a concentration of 8 µg/ml., tritium-labelled cytidine (1 c./mM) at a concentration of 0·2 µg/ml. and ^{14}C-guanine (3 mc./mM) at a concentration of 20 µg/ml. (All labelled materials were obtained from New England Nuclear Corp.) To stop DNA metabolism simultaneously in all flasks, they were plunged into an ice bath, the medium removed, the cells washed twice with phosphate buffered normal saline, and extracted with 4 per cent perchloric acid for 10 min in the cold. RNA and DNA were extracted by either fractional extraction with perchloric acid[10] or by digestion with sodium hydroxide, reprecipitation with hydrochloric acid, and extraction of the DNA with hot perchloric acid[11]. The absorbance of the DNA extract thus obtained was measured at 267 mµ and the DNA calculated by comparison with DNA standards; the radioactivity was determined in a liquid scintillation spectrometer, and the activity calculated as d.p.m./µg DNA.

For autoradiography, incubation with ^{3}HTdR-containing medium (0·036 µg/ml.) occurred for 0·5 h, after which the cells on the cover-slips were fixed with acetic acid–alcohol (1 : 3), washed with distilled water, the cover-slips mounted on 1 in. × 3 in. microscope slides and covered with '*AR*–10' stripping film. With duplicate cultures the cells were treated with 0·02 per cent deoxyribonuclease in 0·002 M magnesium sulphate to remove DNA before the cover-slips were mounted. Some sets of autoradiograms were exposed for 1 week and others for 4 weeks before development.

When HeLa *S*3 cells were grown in normal medium or medium containing TdR the effect of ultra-violet on incorporation of radioactive precursors into DNA followed a similar pattern independent of the precursor used. Fig. 1 shows the results of a number of experiments using different labelled precursors, and, although there is some variation, in all cases the dose-dependent depression appears to consist of at least two components when plotted on a semilogarithmic plot—an initial steep decline in the lower dose range with a decreasing slope at higher doses.

When cells were grown in medium containing 5-BUdR for 2–3 days prior to irradiation the extent of incorporation varied with the type of precursor used, especially at higher doses. (It should be pointed out that just the presence of 5-BUdR in DNA depresses the rate of incorporation of radioactive precursors from 40 to 70 per cent (ref. 1).) The results are summarized in Fig. 2. When 8-^{14}C guanine (3 mc./mM) is used as tracer, the depression of incorporation with increasing dose, compared with its unirradiated control, is nearly the same as that obtained with TdR grown cells. When ^{3}HTdR and ^{14}C-thymidine were used as tracers, the depression of incorporation at low doses was similar to that obtained with cells grown in TdR; however, at doses above 200 ergs/mm^2 the uptake of these tracers began to increase, and at 800 ergs/mm^2 the incorporation was back to 40–50 per cent of the unirradiated control. Qualitatively similar results were obtained with *DFAF*-33 cells.

The results of the autoradiographic experiments with ^{3}HTdR are summarized in Table 1. One-week exposures gave practically identical results, but, of course, with correspondingly reduced grain densities. In normal, unirradiated populations, only those cells synthesizing DNA will show nuclear label after a short period of

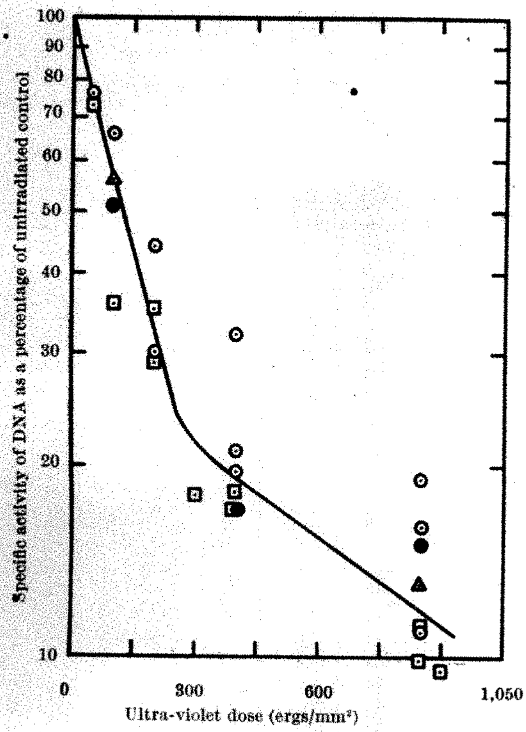

Fig. 1. Incorporation of various tracers into DNA of HeLa cells after two-days growth in Eagle's medium containing 4 μg/ml. TdR, and exposure to ultra-violet. Activity of the DNA was measured as described in the text. The ultra-violet dose was that incident at the surface of the flasks.
(⊡), 8-^{14}C Guanine; (●), 8-^{14}C adenine; (⊙), ^{3}HTdR; (△), ^{14}CTdR

incubation with ^{3}HTdR. The results with *DFAF*-33 cultures were both surprising and revealing. The thymidine-grown cells exhibited no difference in fraction of labelled cells between unirradiated and irradiated cultures, even at high doses (although the intensity of labelling did decrease with increasing dose). However, with BUdR-grown cells, the fraction of labelled cells in irradiated populations was, in all cases, 98 per cent or greater, with only an occasional cell not exhibiting grains above the nucleus. With HeLa the results were even more surprising, and showed a significantly different response from the Chinese hamster cells. With this line not only did irradiated BUdR-grown cells exhibit almost 100 per cent labelling, but so also did thymidine-grown cells. The percentage of labelled cells in unirradiated TdR-grown HeLa cells was unusually high; this may be due to the prior growth in the presence of TdR, which has been shown to affect DNA metabolism[12]. The fact that extension of exposure of labelled *DFAF*-33 cells to autoradiographic emulsion to four weeks did not significantly increase the fraction of cells showing label indicates that the difference between the two strains is really a qualitative one. Treatment with DNase in all cases resulted in depressions of grain count by more than 90 per cent, showing that the label was actually in DNA.

Separate experiments were performed in which all work beginning with the ultra-violet irradiation and thereafter was done in subdued light, using the same conditions necessary to avoid photoreactivation in bacteria. Such procedures had no effect on the results, and intentional exposures of ultra-violet irradiated cultures to 3650 Å light also failed to yield any evidence of photoreactivation of this response.

Table 1. PERCENTAGES OF CELLS SHOWING NUCLEAR LABEL AFTER ULTRA-VIOLET IRRADIATION

Cell type	Medium supplement	Percentage of labelled cells	
		Unirradiated	Irradiated
DFAF-33	TdR	67	62
DFAF-33	BUdR	56	98
HeLa	TdR	53	99 +
HeLa	BUdR	27	99 +

Cover-slip cultures, grown as described in the text, were irradiated with 500 ergs/mm² of ultra-violet at 2537 Å and incubated with ^{3}HTdR at 10 μc./ml. (0·36 μg/ml.) for 30 min at 37° C. Autoradiograms were prepared and exposed for 4 weeks. The percentages are based on counts of at least 500 cells.

These results, showing: (1) increased uptake of ^{3}HTdR and ^{14}CTdR at doses above 200 ergs/mm²; (2) incorporation of ^{3}HTdR by practically every cell in BUdR-grown *DFAF*-33 cultures and in all HeLa cultures following ultra-violet, cannot be explained on the basis of the kind of DNA synthesis occurring normally in these cells. The HeLa cultures show this most clearly. In this line, DNA synthesis (*S* period) normally occurs for 6–7 h of the average 20 h generation time[13]. Therefore about 5 per cent of the cells move into and out of DNA synthesis each hour. The incubation time for some autoradiographic experiments was 0·5 h, and it is inconceivable that a few seconds exposure to ultra-violet could drive all cells into the *S* period. This is especially exemplified by the fact that, following ultra-violet, even cells in mitosis are labelled by an immediate 0·5 h incubation with ^{3}HTdR. In no other circumstance, including after X-irradiation, has this ever previously been observed.

The fact that the increased uptake of tracer at doses above 200 ergs/mm² occurs with ^{3}HTdR at 0·036 μg/ml. and ^{14}CTdR at 8 μg/ml. clearly shows that the effect is not related to pool size changes. The failure of ^{14}C-guanine to exhibit a similar rise indicates that the effect has a certain degree of specificity. Because of the difficulty of obtaining a specific label for the cytosine moiety of DNA, it cannot be definitely concluded, as yet, that only thymine is involved in this phenomenon. However, the enhancement by BUdR of ^{3}HTdR uptake but not of ^{14}C-guanine does suggest that the effect occurs predominantly at areas of DNA containing bromuracil, and the labelling of 99+ per cent of the cells after ultra-violet of non-BU containing HeLa cultures indicates that the presence of BU in DNA makes more apparent the existence of a system that is always active following ultra-violet irradiation.

The most puzzling result is the difference between the two cell lines in extent of labelling following ultra-violet irradiation of thymidine-grown cells. Extending the exposure time of the autoradiograms failed to appreciably increase the fraction of labelled cells in the irra-

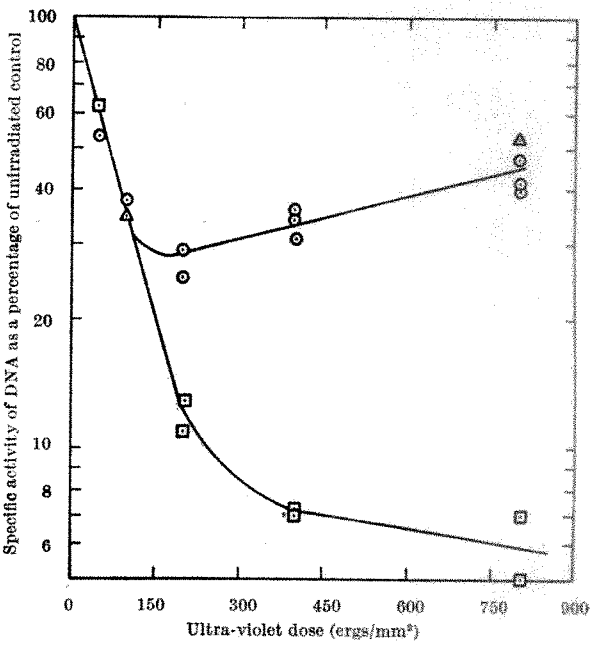

Fig. 2. Incorporation of various tracers into DNA of HeLa cells after two days growth in Eagle's medium containing 5 μg/ml. BUdR, and exposure to ultra-violet.
(⊡), 8-^{14}C Guanine; (⊙), ^{3}HTdR; (△), ^{14}CTdR

diated, thymidine-grown, *DFAF*-33 populations, and it thus appears that cells of this kind that are not in DNA synthesis at the time of irradiation do not participate in the post-irradiation synthesis unless they have previously incorporated BUdR into the DNA.* This difference in the two lines might still be only quantitative, with ultra-violet damage to normal *DFAF*-33 DNA being relatively light (compared with HeLa) but greater with BU substituted DNA; however, the evidence now available suggests that the response to ultra-violet damaged DNA differs qualitatively in the two lines.

The results reported here may involve a system similar to that reported for bacteria by Setlow and Carrier[2] and Boyce and Howard-Flanders[3]. In the case of bacteria the effect was detected by the finding that thymine dimers moved from the acid-insoluble to the acid-soluble fraction in the first hour after ultra-violet irradiation. We have attempted to determine, by pre-labelling the DNA with ^{3}HTdR and ^{14}CBUdR, if thymine or BU in the DNA of cells irradiated with ultra-violet light is lost to the acid-soluble fraction (or to medium, wash fluid, etc.). So far we have found no quantitative increase in material lost from DNA of irradiated cultures over that lost in controls. However, the fraction which would be lost, calculated on the uptake of ^{3}HTdR which occurs, would be so small that it would fall within the variability of our control values. Improved techniques may allow us to detect this loss, if indeed it occurs. To our knowledge, there has been no report indicating that the presence of BU in DNA affects the dark repair occurring in bacteria following irradiation.

We are using the approach of Pettijohn and Hanawalt[4] to determine if the density labelling of DNA following ultra-violet irradiation is different from normal. We are also examining other cell lines to determine the generality of the phenomenon, both in normal and in BU substituted DNA.

CATALYTIC DECOMPOSITION OF GLUCOSE IN AQUEOUS SOLUTION BY THERMAL PROTEINOIDS

By Prof. SIDNEY W. FOX and Dr. GOTTFRIED KRAMPITZ

Institute for Space Biosciences, Florida State University, Tallahassee

THE thermal condensation in an initially dry state of the eighteen amino-acids common to protein[1-3] represents a synthesis by which protein molecules can be visualized as having come into existence simply in a geological matrix[4]. These thermal polymers, proteinoids, readily form membranous microparticles[5,6], have nutritive quality for bacteria[3] and rats[7,8], are split by proteolytic enzymes[2,3], and have their own catalytic activity for the hydrolysis of *p*-nitrophenyl acetate[9], in some cases at a rate many times that observed with the amount of histidine contained in the polymer[9,10].

Preliminary reports of activity for the hydrolysis of ATP at 40° by zinc-containing proteinoids are appearing[11,12]. This communication reports the catalytic activity in aqueous solution of thermal proteinoids for the decomposition of the natural substrate, D-glucose.

The activity observed concerns the decomposition of uniformly labelled ^{14}C-glucose to $^{14}CO_2$ at a low rate of conversion ; some $^{14}CO_2$ production has, however, been measured in every one of more than sixty experiments. Evidence has been obtained that one of the intermediates is glucuronic acid, and radio-glucuronic acid itself has been found to yield $^{14}CO_2$ in the presence of thermal proteinoid, at a rate many times that of the production from glucose. Glucose labelled only in the 6-position showed a comparable rate of production of $^{14}CO_2$, whereas glucose labelled in the 1- or 2-position yielded virtually no $^{14}CO_2$.

In a typical experiment, 100 mg of a 2 : 2 : 1-proteinoid[3] dissolved in 50 ml. of redistilled water was incubated at 37·5° C for 72 h with 10 μc. of uniformly labelled ^{14}C-glucose (specific activity, 28·5 mc./mM; Calbiochem) freshly purified by chromatography. The reaction mixture was maintained under a slow stream of pre-purified nitrogen and the gas was passed through a flask containing saturated barium hydroxide. The carbon dioxide traps were replaced after 1, 2, 3, 6, 12, 24, 48, and 72 h. To each trap was added 50 mg of carrier barium carbonate ; the total carbonate was collected on Whatman No. 50 filter paper after complete precipitation. The precipitate was washed with 50 ml. water and then 20 ml. ethanol. The radioactivity was estimated on a windowless, gas flow beta-detector operated in the Geiger range with helium-isobutane. The counts were determined over 10 min. Controls without proteinoid and others without glucose were run. Measurements of the evolution of carbon dioxide are represented in Table 1.

Mixtures of amino-acids in the proportions found in the analysis of the proteinoid were observed to be devoid of catalytic activity, as were direct hydrolysates (Table 1).

Some increase in rate of evolution of carbon dioxide was observed when ATP or Mg^{++} or both were added to the reaction mixture (Fig. 1). The shape of the curves constitutes part of the evidence ruling out microbial contamination as a source of enzymatic activity. Most of the experiments were at *p*H 2·5, which of course inhibited most or all microbial growth. As a rigorous check on the possibility of contamination, syntheses were carried out aseptically under the supervision of Dr. and Mrs. Lutz Wiese.

The aseptic syntheses began with amino-acid mixtures which had stood under diethyl ether for 48 h and which had

Principles of the Theory of Solids

J. M. ZIMAN

A clearly-written graduate course based on the author's experience of teaching such courses in England and the United States. The book is concerned with the fundamental principles, rather than detailed accounts of various phenomena; in each case, a self-contained mathematical treatment of the simplest model which will demonstrate the phenomenon is given. *45s. net*

Packing and Covering

C. A. ROGERS

An account of the theory of packing and covering in *n*-dimensional space, where *n* is larger than 3. The approach is quantitative and many estimates for packing and covering densities are obtained. The history of the subject is outlined in the introduction; succeeding chapters contain a systematic account of the general results and their derivation. *Cambridge Tracts in Mathematics, No. 54* *30s. net*

Atomic spectra

CHRIS CANDLER

This book states the facts, which may all be hung on the vector model, and lets the theory emerge; the argument remains within the easy comprehension of every working physicist. Valuable even to past-masters of the subject is the book's appendix of Grotrian diagrams for all arc spectra except those of the rare earths and for the few spark spectra that yield strong lines in the arc.

October publication. Second edition. £5 5s.

Newer Methods of Polymer Characterization

edited by BACON KE, *C. F. Kettering Research Laboratory, Yellow Springs, Ohio*

This collection of recently developed methods for characterizing synthetic and natural macromolecules is Volume 6 in the *Polymer Review Series*. The chapters have been written by people active in the field. These writers point out how these methods have been and/or can be applied.

744 pages, 185s.

Treatise on Analytical Chemistry

Part I, Volume 4

edited by I. M. KOLTHOFF and P. J. ELVING, *both of University of Michigan*
with the assistance of E. B. SANDELL, *University of Minnesota*

The most comprehensive work available in its field, this book covers all the electrical techniques used in chemistry, primarily from the point of view of the analytical chemist. It will be of interest to process and other chemical engineers owing to the great importance of electrical methods for industrial control and automatic methods of analysis.

954 pages, 189s.

Titrimetric Organic Analysis

Part I : Direct Methods

M. R. F. ASHWORTH, *Professor of Applied and Analytical Organic Chemistry, University of the Saar, Germany*

This book is volume 15, part 1 in the series *Chemical Analysis*. It provides a comprehensive compilation and classification of data and references on the titration of organic compounds and materials, including methods of end-point determination, the characteristics of reagents, and methods of analysis for functional groups and substances.

512 pages, 132s.

Electromagnetic Slow Wave Systems

R. M. BEVENSEE, *Assistant Professor of Electrical Engineering, University of California*

Describes the electromagnetic properties of many microwave accelerators and amplifier structures and the theoretical performance characteristic of various electron beam amplifiers. The analysis is based upon a powerful and widely applicable variational method for obtaining propagation constants.

464 pages, 132s.

Nuclear Interactions

S. DEBENEDETTI, *Professor of Physics, Carnegie Institute of Technology*

The graduate student who is grounded in quantum mechanics will find in this text-reference a description of the basic facts and a clear presentation of the theory of fundamental nuclear interactions. The volume will also be of interest to the professional nuclear experimentalist who desires a source of more complete and more accessible presentation of the theory than is usually available in a single volume.

636 pages, 120s.

Essays 1958/62 on Atomic Physics and Human Knowledge

NIELS BOHR. *With a preface by* A. BOHR, *Professor, Institute of Theoretical Physics, Copenhagen*

The essays collected in this volume show the difficulties encountered by physicists when they explored the atom, and also how changes in the field of physics have influenced not only the scientific outlook but all branches of human knowledge.

107 pages, 30s.

Introduction to Advanced Field Theory

G. BARTON, *The Clarendon Laboratory*

This book is Volume 22 in the series *Interscience Tracts on Physics and Astronomy*, edited by R. E. Marshak. Based on lectures given at the Clarendon Laboratory, it emphasizes the field theory of elementary particles, and orients the reader towards what can and cannot be done without reference to the iterative solution. The author assumes the reader is acquainted with the outlines of covariant perturbation theory and with Feynman diagrams. In elementary terms, he explains why the problems treated and others like them are of interest in physics, and presents enough basic detail and discussion so that the reader can assimilate current papers in this field, with a reasonably clear understanding of their relevance to the theory as a whole.

176 pages, 49s.

Theory of Spin Relaxation

W. J. CASPERS, *Institute of Crystal Physics, Groningen*

Volume 6 in the series *Monographs in Statistical Physics*, edited by I. Prigogine. It gives a detailed theoretical analysis of paramagnetic relaxation phenomena, in particular those processes in which the interaction between the elementary dipoles plays a predominant role (spin-spin relaxation).

160 pages, 75s.

Maternal Behavior in Mammals

edited by Harriet L. Rheingold, *National Institute of Mental Health*

Each chapter of this book reports the current research findings of an investigator on the maternal behaviour of the mammal he has been studying. The investigators have described and measured the behaviour of the mother in the presence of her young; how her behaviour affects the behaviour of her young; how other members of the mother's group respond to the young; how the mother accepts or rejects their attention to her offspring; and how at a certain stage the mothers of some species withdraw from the young and punish the young for seeking contact with them.

349 pages, 66s.

The Design of Electric Circuits in the Behavioral Sciences

Tom N. Cornsweet, *Associate Professor of Psychology, University of California, Berkeley*

This book is about the basic circuitry and building blocks of the kind of electrical apparatus that is used in research on behaviour. It is directed at the scientist who has had little or no training in electrical and electronic techniques. The text combines basic electrical theory with pictures and descriptions of real pieces of electrical apparatus in such a way that the reader can achieve the capacity to design and construct complex switching and timing circuits that meet the needs of his own research, and can understand the principles underlying complex electronic equipment.

340 pages, 68s.

Motivation: Theory and Research

C. N. Cofer, *Professor of Psychology, Pennsylvania State University*
and M. H. Appley, *Professor and Chairman, Department of Psychology, York University, Toronto*

Workers in the behavioural sciences, at whatever level, from upper level, undergraduate to full-time researchers, will find here the most comprehensive review of the theoretical and research literature of motivational psychology in print anywhere. The authors compare and evaluate the major theoretical concepts and positions in the field of the past 50 years. They review recent and significant research in areas associated with motivation, ranging from studies of sex, hunger, and sleep to recent work in ethology, cybernetics and psychoanalysis. Notable is the extensive bibliography prepared for this publication.

976 pages, 94s.

The Precambrian
Volume I

edited by K. Rankama, *University of Helsinki*

This work, the first part of a new series "The Geologic Systems," is of special interest for the geologist as it deals with the assessment of exact ages which can be ascertained by the dating methods based on radioactive decay. For this and other reasons there is a growing interest for the Precambrian which is by far the greatest part of the geological history of the earth.

280 pages, 68s.

Highway Engineering
Second Edition

C. H. Oglesby, *Professor of Civil Engineering, Stanford University*
and L. I. Hewes, *Late Chief, Western Headquarters, U.S. Bureau of Public Roads*

Largely rewritten to reflect the great changes in highway knowledge and to delineate new methods and trends. The updated and newly incorporated material includes: problems of urban land use and transportation planning; the impact of photogrammetry, computing, and other recent developments on highway location practices; recent findings on the interaction between soil and moisture with reference to design and construction procedures.

791 pages, 84s.

Tractors and Their Power Units
2nd Edition

E. L. Barger, *Manager, General Product Planning, Massey-Ferguson Ltd.*
J. B. Liljedahl, *Professor, Agricultural Engineering Department, Purdue University*
W. M. Carleton, *Associate Director, Agricultural Engineering Research Division, ARS, U.S. Department of Agriculture*
and E. G. McKibben, *Director, Agricultural Engineering Research Division, ARS, U.S. Department of Agriculture*

The authors of this book offer a complete discussion of all technical aspects of farm tractors, both in theory and performance, in design and operation from engine to accessories. Considerable discussion is given to the internal combustion engine. Although intended for the engineering student who has a solid basic knowledge of principles, the authors believe this new edition will be even more useful as a guide to the farm equipment engineer, and others desiring a readily available source on tractor design and usage.

NEW HEYWOOD BOOKS

TRANSISTOR CIRCUITS
2nd Edition
K. W. Cattermole

The text of this well-known work has been completely revised and brought up to date for the new edition. A valuable, easily understood introduction to the subject suitable for radio and electrical technicians, students and interested amateurs. A classified bibliography provides sources of further information.

Demy 8vo. Illustrated. 483 pages. **70s.**

GEM TESTING
7th Edition
B. W. Anderson

The new 7th edition of this standard work (to be published next month) includes completely rewritten chapters on Zircon and Garnets, and considerably expanded ones on Fluorescence and Synthetics. A new chapter on the collection of gem stones, and instruments used by collectors and dealers, has been added.

Demy 8vo. Illustrated. 400 pages. **50s.**

DISCHARGE DETECTION IN HIGH VOLTAGE EQUIPMENT
F. H. Kreuger

The book describes the phenomena relating to discharges and the mechanisms leading to electrical breakdown, together with a systematic review of existing measuring techniques and recommended methods for testing high voltage equipment.

DIN A5. Illustrated. 225 pages. **60s.**

Optical Transforms

Their Preparation and Application to X-ray Diffraction Problems

C. A. TAYLOR and
Professor H. S. LIPSON
both of the Faculty of Technology, University of Manchester

The aim of this book is two-fold: to introduce a new research tool to X-ray crystallographers; and to provide a basis for teaching Fourier transform ideas in general through the visual medium of optical transforms. Methods are illustrated by many practical examples and there are 54 very fine plates of optical transforms, many of which show several subjects.

Numerous figures in the text. 45*s. net.*

The Faraday Press announces 21 major Soviet Scientific Journals now available for the first time

- **AUTHORITATIVE COVER-TO-COVER ENGLISH TRANSLATION**
- **REGULAR YEARLY SUBSCRIPTION - BEGINNING WITH JAN. 1965 ISSUES**

Nuclear Physics / *Yadernaya Fizika*
Soviet progress at the Kurchatov Institute, at Dubna and other key centers, previously reported in various journals, will now be covered by this indispensable Academy of Sciences publication. *Monthly, $155 / year*

Differential Equations / *Differentsial'nyye Uravneniya*
Offers for the first time in a single journal the original work of outstanding Soviet mathematicians in this increasingly important field. *Monthly, $155 / year*

Theoretical and Experimental Chemistry / *Teoreticheskaya i Eksperimental'naya Khimiya*
Reports on the most important current research of the leading centers throughout the Soviet Union; the equivalent in importance in chemistry to the Soviet J. Theoretical & Exp. Phys. in physics. *Bimonthly, $125 / year*

Soviet Radiophysics / *Izvestiya VUZ. Radiofizika*
Presents original contributions by Troitskiy and other world-famous Soviet radiophysicists dealing with lunar and solar radio emission, the propagation of electromagnetic waves, and other radiophysical phenomena. *Bimonthly, $130 / year*

Soviet Radio Engineering / *Izvestiya VUZ. Radiotekhnika*
Publishes articles on the latest Soviet advances in information theory, high-frequency radio electronics and electrodynamics, and new radio engineering materials and components. *Bimonthly, $120 / year*

Journal of Applied Mechanics and Technical Physics / *Zhurnal Prikladnoy Mekhaniki i Tekhnicheskoy Fiziki*
A wide-ranging journal of importance to applied physicists, and mechanical, aeronautical, chemical, and structural engineers. *Bimonthly, $155 / year*

Soviet Physics / *Izvestiya VUZ. Fizika*
Covers advanced Soviet theoretical and experimental investigations in plasma physics, optics, molecular physics, electronic processes and the entire range of physics research. *Bimonthly, $130 / year*

Astrophysics / *Astrofizika*
Describes Soviet research in lunar, interplanetary, solar and stellar physics, as performed under the direction of V. A. Ambartsumyan and other leading astrophysicists. *Quarterly, $95 / year*

Polymer Mechanics / *Mekhanika Polimerov*
Keeps the reader informed on the latest and most valuable developments in Soviet polymer research and applications. *Bimonthly, $125 / year*

Heat and Power / *Teploenergetika*
Reports the latest advances in heavy power equipment and automation, fuels and combustion, turbomachinery design, and thermophysical properties. *Monthly, $225 / year*

Applied Solar Energy / *Geliotekhnika*
A significant new journal, devoted entirely to a subject in which Soviet scientists are making outstanding contributions. *Bimonthly, $115 / year*

Journal of Organic Chemistry / *Zhurnal Organicheskoy Khimii*
Of interest to every Western organic chemist, this new journal will be the principal source of information on Soviet research in this field, previously available only as scattered articles in many journals. *Monthly, $165 / year*

Journal of Applied Spectroscopy / *Zhurnal Prikladnoy Spektroskopii*
Describes the many expanded and new applications of spectroscopy in the various engineering and scientific disciplines. *Monthly, $155 / year*

Journal of Engineering Physics / *Inzhenerno-Fizicheskiy Zhurnal*
Devoted to Soviet basic and applied research in heat and mass transfer and exotic heat sources; highly valuable, presenting many original contributions. *Monthly, $155 / year*

Magnetic Properties of Liquid Metals / *Magnitnaya Mekhanika Zhidkikh Metallov*
Increasing research and success in technological applications of magnetism in the Soviet Union have led to the publication of this important new journal. *Quarterly, $95 / year*

Chemistry of Heterocyclic Compounds / *Khimiya Geterotsiklicheskikh Soyedineniy*
Expanding Soviet research in this increasingly important area has contributed this vital new journal. *Bimonthly, $125 / year*

Chemistry of Natural Compounds / *Khimiya Prirodnykh Soyedineniy*
The Soviet journal devoted to original research in the structure, modification and synthesis of natural compounds. *Bimonthly, $115 / year*

Electrical Engineering / *Elektrotekhnika*
Reports the latest, most important advances in Soviet electrical equipment and instrumentation. *Monthly, $165 / year*

Applied Biochemistry and Microbiology / *Prikladnaya Biokhimiya i Mikrobiologiya*
Research in this field is producing extensive and valuable new applications in many areas of industry and medicine; reviewed fully in this critically important new journal. *Bimonthly, $125 / year*

Physicochemical Properties of Materials / *Fiziko-Khimicheskaya Mekhanika Materialov*
Of great importance to industry, this journal reports on new materials being developed in the Soviet Union, their properties and specific applications. *Bimonthly, $120 / year*

Cybernetics / *Kibernetika*
Offers a complete review of current achievements and long-range goals in this field being rapidly developed in the Soviet Union, in which top Soviet talent is being concentrated. *Bimonthly, $120 / year*

Note: Yearly subscriptions and back copies (1962-current) to "Soviet Engineering Physics Abstracts" and "Soviet Heat and Power Abstracts" are still available—write for further information.

Order your 1965 subscriptions to the essential Soviet journals described above from:

A New Edition of the Unrivalled Classic

PRINCIPLES OF PHYSICAL GEOLOGY

Completely Revised—
Greatly Enlarged

Professor ARTHUR HOLMES

Since its original publication in 1944, *Principles of Physical Geology* has profoundly influenced the thinking and training of geologists throughout the world.

This new edition has been almost entirely re-written, since geology itself has expanded considerably, and incorporates discoveries made as recently as 1963–64. These include the dating of earth history; salt domes; marine sediments and the ocean floor; mountain building by gravity gliding; palaeomagnetism of rocks and continental drift, etc.

Ten chapters have been added to the original edition and many more have been considerably enlarged. Over 400 new illustrations, many of them particularly beautiful, are also included.

Professor Holmes' standing in the world of geology could not be higher. He was of course recently awarded the Vetlesen Prize for 1964.

1,184 *pages. Nearly* 900 *half-tone illustrations and line drawings. October* 84*s*

NELSON

NUMERICAL METHODS: II
DIFFERENCES INTEGRATION AND DIFFERENTIAL EQUATIONS

BEN NOBLE

The second volume of *Numerical Methods* is almost independent of Volume I. It deals with those aspects of numerical analysis which are based on finite difference techniques and includes sections on polynomial interpolation; numerical integration and differentiation; and numerical solution of ordinary and partial differentiation. Particular attention is paid to the treatment of errors. The author has been at pains to examine points of difficulty which have arisen in actual computations. The common practice of regarding numerical analysis as a collection of recipes has been avoided; instead of listing all possible methods, general principles are illustrated by discussing some of the more important methods in full detail.

PROBLEMS OF RADIATION GENETICS

N. P. DUBININ

Translated by G. H. BEALE
Genetic Dept., Edinburgh University

This book gives a concise account of the effects of different forms of radiation on living organisms, and includes a very thorough report of Russian contributions to the subject as well as those of Western workers. The topics covered include the basic principles of classical cytogenetics; the physical aspects of the action of radiation on living organisms; the effect of ionising radiations on genetic properties of animals, plants and micro-organisms; and the action of ultra-violet and visible light on heredity. Special attention is given to the effect of radiation on mammalian and human heredity.

The author also considers the danger to man of increased amounts of radiation in the atmosphere from radioactive fall-out, the hazards to pilots of spaceships from cosmic radiation, and the more positive applications to plant and animal breeding.

MICROMANIPULATORS

if you use a
MICROSCOPE
you need a
SINGER
FULLY PATENTED
MICROMANIPULATOR

Singer micromanipulators are used in most laboratories all over the world.
Three types available:
Mk I Low power for magnifications ×1 to ×200
Mk II For magnifications ×1 to ×500
Mk III High power for magnifications ×100 to ×1,000 *plus*
The most advanced instruments for micromanipulation. As described by Barer and Saunders-Singer with further improvements.
Full details and demonstrations upon request to :

SINGER INSTRUMENT CO. LTD.,
Fountain Court, 83 London St.,
Reading, Berkshire, England.

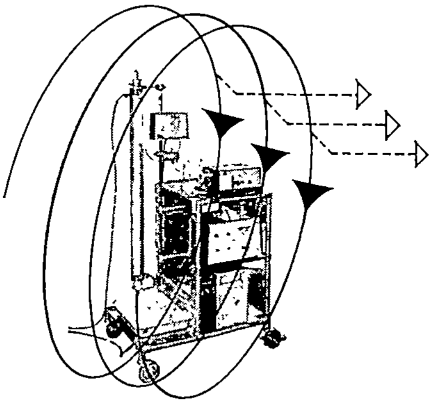
Introducing the LKB ReCyChrom for

RECYCLING CHROMATOGRAPHY

NEW INSTRUMENTATION FOR A NEW TECHNIQUE* IN CHROMATOGRAPHIC SEPARATION



The ReCyChrom is equally applicable for preparative and analytical separation of mixtures of large-sized or of small-sized molecules. These molecules do not have to be electrolytes and restrictions on the type of buffer used are less than with other types of chromatography. Components within a narrow range of molecular sizes, usually not resolved on simple gel filtration columns, are separated in the ReCyChrom by allowing the sample to pass repeatedly through the bed, thereby multiplying its effective height many times. Separated fractions and uninteresting or disturbing parts of the effluent may be bled out of the stream after any cycle without interrupting the separation of the remaining components.

The apparatus is especially suitable for grading homologous series of polymers, e.g., dextrans; for routine control of the purity of biochemical preparations such as serum proteins, enzymes and hormones; and for separation of heat labile substances.

One unique advantage of recycling chromatography is the need for columns of only moderate length. Columns in two standard lengths, 60 cm and 100 cm, both with 32 mm bore are available at present. The range of sample volumes accommodated by these columns depends greatly on the nature of the sample. For simple desalting operations or for separation of peptides and amino acids from proteins, a sample of up to *150 ml* is not unusual, whereas for purity controls of radioactively tagged concentrated preparations, quantities down to 1/100 of this volume are feasible. Sample application by pipette is eliminated. The pump sucks sample through a selector valve with a holdup of 150 µl—a reproducible and non-critical method.

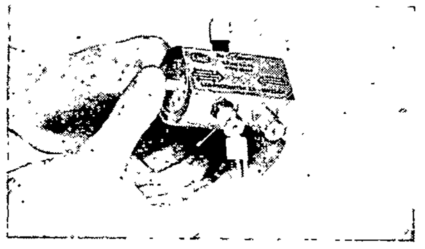
The four main components of the ReCyChrom, namely, a separation column, a peristaltic pump, a selector valve and a flow analyzer are available separately for incorporation into other instrument setups. The specially constructed columns with adjustable plungers at both ends can be sealed completely to eliminate the pressure of water head and permit liquid flow in either direction. Closed system operation and ascending flow maintains even packing and prevents the flow rate from falling off with use, even when beds of material with low mechanical strength (gels) are used.

LKB's specially designed peristaltic pump has a very high flow constancy—0.5% over a period of a week—and a continuously variable pumping rate from 0-390 ml/hr.

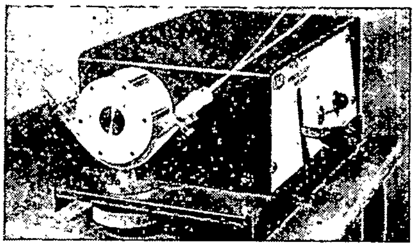
A choice of three flow analyzers, cooling jackets, terminal box, connections and a cart comprise the remainder of the assembly.

*According to J. Porath and H. Bennich

Request literature file 4900N9 for details.



The simple push of a button on the Selector Valve alters the flow circuit from injection or bleeding to recycling.



The Peristaltic Pump has many other uses when not in service for the ReCyChrom.

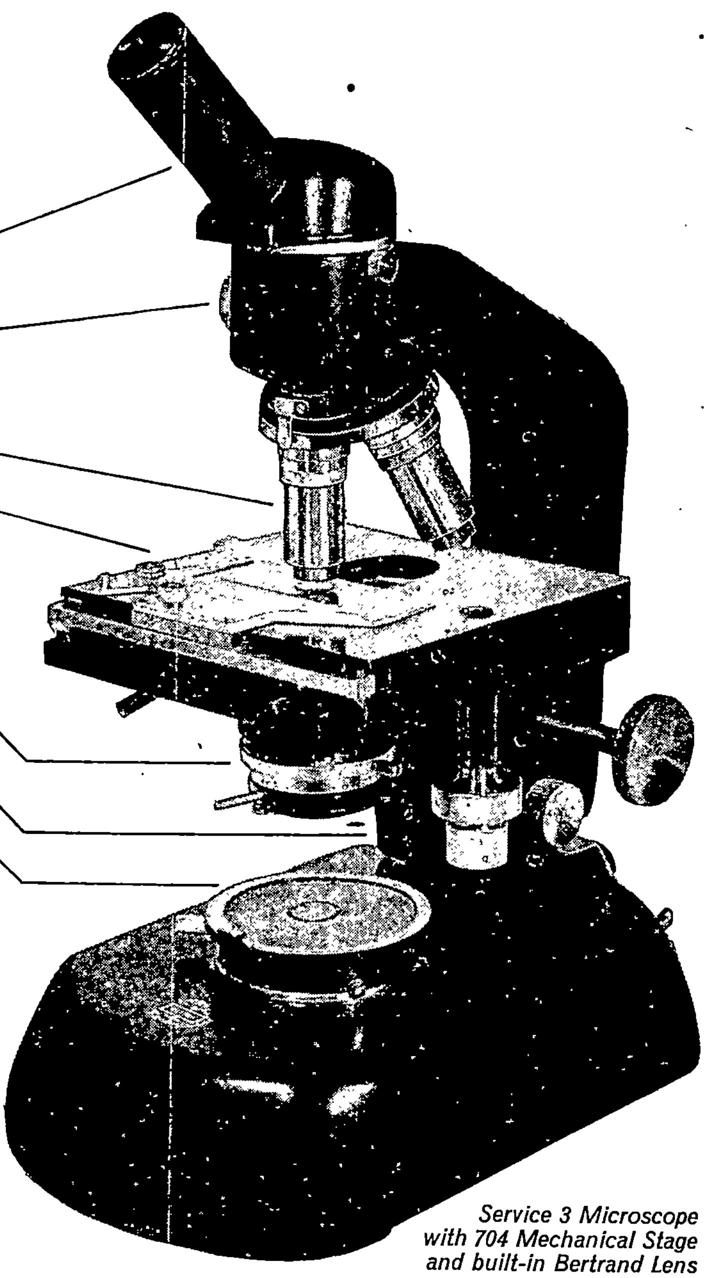
LKB PRODUKTER AB, P.O. Box 12220, Stockholm 12, Sweden

NEW FROM

WATSON



rotating inclined monocular head

Bertrand Lens control knob

phase plates fitted to standard objectives

704 flat top mechanical stage

standard achromatic substage condenser in centring mount

low-placed concentric control heads for mechanical stage

annulus centring attachment with lamp condensing lens

Service 3 Microscope with 704 Mechanical Stage and built-in Bertrand Lens

LOW-COST PHASE CONTRAST FOR SERVICE 3

The new Watson Phase Contrast accessory meets the demand for robust, low-cost equipment for student use. Designed for the Service 3 Microscope, the accessory is available with either built-in Bertrand Lens or with auxiliary Telescope for easy setting. Operating principles are identical with the Watson Research Phase Contrast outfit and results are of the same high quality.

704 Mechanical Stage

The 704 Mechanical Stage is a new flat top mechanical stage with low placed co-axial control heads, supplied on the Service 3 Microscope as an alternative to the plain stage. Exceptionally smooth vertical and horizontal movements are provided by a patented mechanism which is self-compensating for wear and ensures complete freedom from losses.

Added Advantages

An improved location of the head (monocular or binocular) provides smooth, 360° rotation (free from locking screws and easily interchangeable), and a new mechanism for stage fine adjustment focusing gives precise, controlled movements with maximum built-in reliability. Both coarse and fine adjustment controls have been rigorously life-tested.

The Service 3 is now available in semi-matt black enamel. Please write for full details.

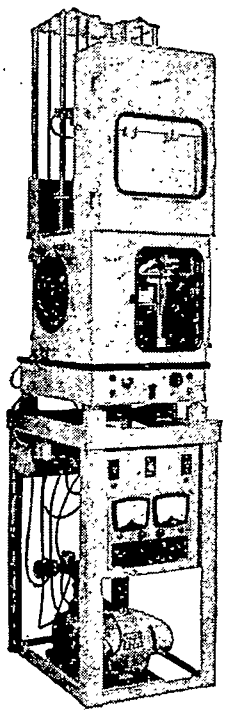
Massflow



The Stanton 'Massflow' Vacuum Thermobalance records changes of weight as a function of temperature and time, for samples heated under vacuum, controlled atmosphere or continuous gas flow.
The apparatus includes furnace, programme controller, gas- and vacuum-tight sample tube, automatic weight-loading analytical balance, and a twin-pen chart recorder. Alternative furnaces give temperature range up to 1000°C or 1350°C.
Pumping equipment for vacuum down to 10^{-4} torr can be fitted. Balance sensitivities of 1 mg. per division and 0.1 mg. per half division are available.

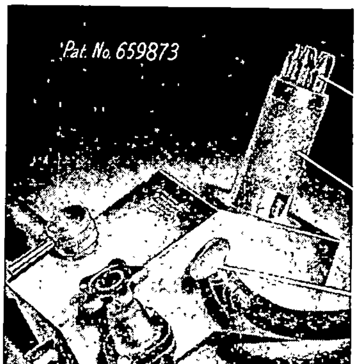
The SCORAH OXY-COAL GAS BLOW PIPE



specially for working **BOROSILICATE GLASSES (Pyrex, Phoenix, Hysil, etc.)**

- Five jets and central pilot light — flame size selected INSTANTANEOUSLY.
- Rotating turret head for easy jet selection.
- Auxiliary supply of oxy-coal mixture for hand torch.

Minimum oxygen consumption
Maximum economy

A modern oxy-coal gas blow-pipe of sturdy construction evolved through years of practical experience in glass manipulation. A nearly silent flame from pin point to one capable of working 100 mm. tubing at a flick of the turret. To the inexperienced it gives confidence, to the experienced it is an assurance of efficiency and successfully completed work. A unique instrument for the research laboratory or workshop. Send for Leaflet BP/N2.

Obtainable only from Price **£25.0.0**

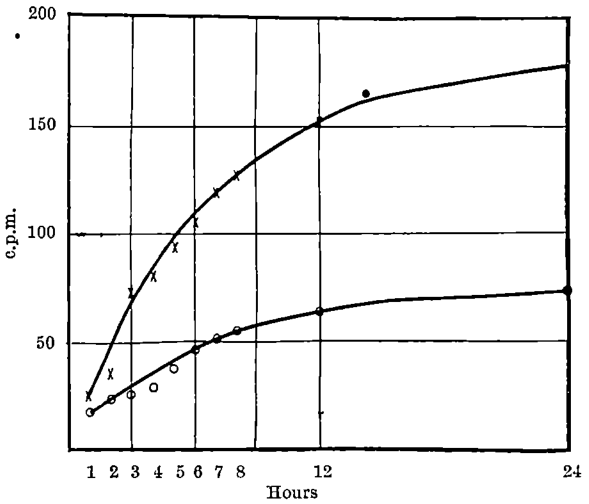

Fig. 1. Evolution of $^{14}CO_2$ from radioglucose in presence of thermal proteinoid, demonstrating the carbon dioxide formation from glucose in the presence of proteinoid. O, shows carbon dioxide evolution for the reaction mixture without any additions; ×, indicates carbon dioxide production from the reaction mixture in the presence of 2·5 μM ATP

no catalytic activity *per se*. The acid proteinoids thus prepared were each tested for sterility in tryptone glucose beef extract: (*a*) broth; (*b*) agar, in tryptone glucose yeast extract; (*c*) broth and (*d*) agar, before dialysis of the proteinoid, after dialysis for 4 days, after resolution of aseptically lyophilized polymer and at the end of the tests for catalysis. The polymers thus prepared showed at least the usual amount of activity after having given negative results for growth in the sterility tests. Lysine proteinoid was also synthesized under sterile conditions. Both the aseptically synthesized lysine proteinoid and lysine proteinoid prepared months earlier, and stored in the usual way in a bottle, were found to be bacteria-free ; this latter probably reflects the bacteriostatic activity of polylysine[13].

As Table 1 shows, thermal lysine proteinoid[9], as first prepared by Dr. Harada[9], was more active than thermal acid proteinoid.

Other sugars, radio (fructose) and radio (sucrose), also yielded $^{14}CO_2$, but in smaller proportions than did (radio) glucose. In three experiments, 10 μc. of sucrose yielded 130, 212, and 316 c.p.m. Such results with sucrose help to rule out the possibility that decarboxylation is due to a Maillard reaction between proteinoid and the sugar[14]. Study of the *p*H activity curve for lysine proteinoid also revealed *p*H optima at 2 and 5, whereas the Maillard reaction is favoured in alkaline solution[14]. The proteinoids were active over the entire range of *p*H 1–9 tested. Activity was only slowly destroyed by heating in aqueous solution. Microspheres[5,6] formed in the steam autoclave from hot water also displayed activity for the evolution of carbon dioxide. An experiment in which a second charge of substrate, added after three days, was decomposed as rapidly as the first charge represents one experiment to test whether the activity is truly catalytic.

For analytical purposes, the reaction mixture was concentrated in a rotary evaporator and finally dried in a vacuum desiccator over sodium hydroxide pellets and over sulphuric acid. The dried residue was three times extracted with dry pyridine in order to remove unreacted glucose; the pyridine extract was taken to dryness over sulphuric acid. Aqueous solutions of the residue from pyridine extract and from the pyridine-insoluble residue were separately subjected to paper chromatography. The samples were applied to Whatman 3*MM* paper. The developing solvent usually was ethyl acetate: pyridine : water (12 : 5 : 4). Chromatography was carried out by ascension (Fig. 2). Fig. 2 presents the initial results.

Following the suggestion of glucuronic acid as an intermediate from the experiment with 6-^{14}C-glucose, this acid was sought as follows. The reaction mixture was made alkaline to phenolphthalein with barium hydroxide. Carbon dioxide was bubbled through this mixture for a few minutes. The mixture was then heated to 100° for 10 min, filtered, and the precipitate was washed with boiling water. The combined filtrates and washings were concentrated to 2 ml. *in vacuo* and mixed with 100 ml. ethanol. The barium salts were collected by filtration and washed with ethanol. The radioactive precipitate was acidified with acetic acid in aqueous suspension and the barium was removed with 1 N sulphuric acid, the liquid dried, and extracted with ethanol. The extract was subjected to two-dimensional paper-chromatography[15] with phenol : deuterium oxide (100 g : 39 ml.) in the first direction and butan-1-ol : propionic acid : water in the second direction. (For this chromatography, two solutions were prepared. Solution *A* contained 919 ml. of butan-1-ol and 81 ml. distilled water. Equal volumes of solutions *A* and *B* were mixed just before use.) One of the spots had the R_F of glucuronic acid as determined with a control. The material was eluted and rechromatographed in ethyl acetate : pyridine : water (120 : 50 : 40). The R_g $\left(R_g = \frac{\text{distance substance travels from origin}}{\text{distance glucose travels from origin}} \times 100\right)$ of the sample, corresponding with that of glucuronic acid. was 13–14. This eluted spot was rechromatographed in methanol : formic acid : water (30 : 15 : 5 v/v), again indicating glucuronic acid.

From an experiment on 3·0 g of glucose (100 mg proteinoid), the isolated glucuronic acid fraction was subjected to reaction with carbazole[16] to give a positive colour test. The maximum absorbance was at 530 mμ, the same maximum being found with the carbazole reaction product of authentic glucuronic acid.

In another reaction of 100 mg of 2 : 3 : 1-proteinoid. 10 g of D-glucose and 10 μc. of U-^{14}C-glucose the extract, following barium sulphate formation and ethanol extraction, was dried in a desiccator. The residue was dissolved in 10 ml. of 0·2 N sodium acetate and 100 mg *p*-bromophenylhydrazine hydrochloride was added. The suspension was heated to boiling for 5 min and 50 mg authentic non-radioactive glucuronic acid *p*-bromophenylhydrazone was added. The suspension was chilled for 2 days. The solid was filtered, dissolved in hot 60 per

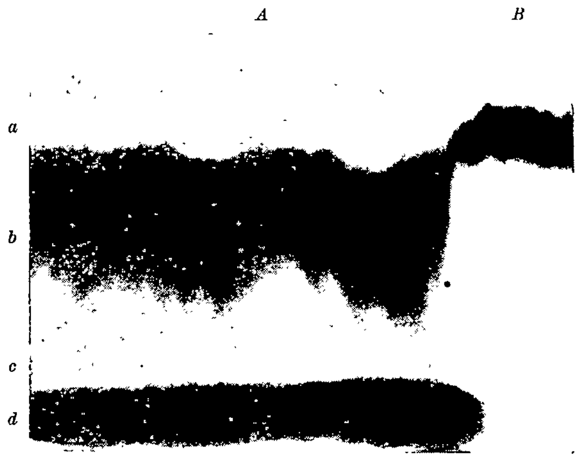

Fig. 2. Autoradiogram of decomposition of radioglucose catalysed by thermal proteinoid. Fig. 2 demonstrates the decomposition products of U-^{14}C-glucose, after incubation with a lysine proteinoid, in a solvent system of ethyl acetate : pyridine : water (12 : 5 : 4) ascending technique; Whatman No. 3*MM* paper. *A* is the water-soluble extract of the reaction mixture. *B* is the water-soluble extract of the reaction mixture before incubation. Bar *a* corresponds to glucose; *b* is unidentified, but does not contain free glucose after rechromatography since it is insoluble in pyridine. On rechromatography, R_F of glucose = 0·27, R_F of major spot = 0·22. Bar *c* has R_F identical with that of glucuronic acid after rechromatography in other solvent systems. Bar *d* is unknown, contains no free glucose or free glucuronic acid

cent ethanol and left in the refrigerator for 48 h. This recrystallization was repeated 4 times. The yellow needles m.p. 236° C unc.[17] mixed m.p. 236° C unc. When examined in a planchet with a window-less counter, 3,700 c.p.m. were recorded. Following a sixth recrystallization, 3,700 c.p.m. were again recorded.

The radioactive *p*-bromophenylhydrazone was chromatographed in water saturated with butan-1-ol. The R_F for this material on an autoradiogram and for cold material observed visually was in each case 0·89. A mixed chromatogram showed also $R_F = 0·89$.

The evidence thus indicates that at least a small fraction of the glucose is first converted to glucuronic acid, which is then decarboxylated, and that each of these reactions is catalysed in aqueous solution by proteinoid prepared by thermal condensation of dry amino-acids mixed in appropriate proportions. Fig. 2 is an autoradiogram which is part of the evidence that the glucose is more than 90 per cent converted to other materials.

These results may explain many earlier findings in this laboratory in which were observed activities for other natural substrates; the variability of such results since 1958 was such that no report had been submitted for publication. This variability now appears to be explainable in part as due to the presence of several weak activities. The evolutionary value of weak catalytic activities, such as compared with those of contemporary enzymes and as here demonstrated for production of polymers active in producing carbon dioxide and glucuronic acid, has been expounded in theoretical treatments particularly by Calvin[18].

The finding of catalytic activities for natural substrates and of integrated nutritive qualities in thermal proteinoids entitles them to be considered both as synthetic general protein and as a model of primitive abiotic protein. In the latter context a catalytic proteinoid which forms organized units[4–6] is conceptually consistent with an evolution which led to diversified, specialized, and quantitatively enriched catalysts.

We thank Dr. and Mrs. Lutz Wiese for help with the aseptic preparations; Dr. David H. Durant for repeating the key experiment demonstrating production of carbon dioxide and intermediates from written directions only; and David Joseph and Sylvia Steen for repetitions of the key experiment. We also thank Dr. Harry Lipner for the use of counting equipment.

The investigation was supported by grant *NsG*–173–62 of the National Aeronautics and Space Administration.

A VARIATION IN THE ELECTROPHORETIC PATTERN OF HUMAN ERYTHROCYTE CARBONIC ANHYDRASE

By Dr. RONALD F. RIEDER and Dr. DAVID J. WEATHERALL

Department of Medicine, Johns Hopkins University School of Medicine and Hospital,
Baltimore, Maryland

CARBONIC anhydrase is the most abundant soluble non-hæmoglobin protein in human erythrocytes[1,2]. At least two and perhaps three distinct proteins in red cells have carbonic anhydrase activity[1,3,4]. The two principal forms, now designated by agreement as *B* and *C* (ref. 4), differ markedly in amounts present and in activity[1,3–5]. Enzyme *B* occurs in 5–10 times greater amount than enzyme *C* (refs. 4 and 5). The specific activity of enzyme *C* is 20–30 times as great as that of enzyme *B* (refs. 1 and 4). The molecular weights of the two forms are quite similar, but the amino-acid compositions differ significantly[3,4,6,7]. Enzymes *B* and *C* are easily separated by starch-gel electrophoresis at alkaline *p*H, enzyme *B* moving more rapidly towards the anode[4,8].

During the course of an investigation of abnormal hæmoglobins, blood samples from approximately 1,400 adults and 1,000 neonatal infants were examined. The hæmolysates were examined by starch-gel electrophoresis[9–11] and the gels were stained with benzidine and amido black 10*B*. As has been previously reported[2], the carbonic anhydrase bands were absent or markedly reduced in intensity in all the hæmolysates made from cord blood (Fig. 1). On electrophoresis of hæmolysates from the adults, using a *tris*-EDTA-borate buffer system[11], at *p*H 8·6, enzyme *B* moved slightly more slowly towards the anode than hæmoglobin A_2 (Fig. 1). Enzyme *C* moved a short distance from the origin towards the cathode (Fig. 2). The only variation noted in the 1,400 adult specimens was an almost complete absence of enzyme *B* in the hæmolysate from a 31-year-old Negro woman (R. M.) (Fig. 1). Unlike the cord bloods, the hæmolysate from R. M. contained carbonic anhydrase *C* and hæmoglobin A_2 (Figs. 1 and 2).

Fig. 3 is the pedigree of the family of R. M. An investigation of the family revealed no other person with the abnormal carbonic anhydrase pattern (Fig. 4). The peripheral blood smear of R. M. was characteristic of thalassæmia minor and the percentages of hæmoglobin A_2 (4·0 per cent) and hæmoglobin F (4·4 per cent) were elevated. The father of R. M. and her three daughters had peripheral blood smears suggestive of thalassæmia minor. The blood of the mother of R. M. was normal except for a hæmoglobin A_2–B_2 electrophoretic pattern (Fig. 4). No other family member had thalassæmia minor. Extensive blood grouping investigations revealed no incompatibility between R. M. and either parent.

Total carbonic anhydrase activity in the erythrocytes of R. M. was assayed by an electrometric method[12] and found to be normal. As has been previously reported[13] enzyme activity was quite low in cord blood. The hæmolysate of R. M. was subjected to starch-gel electrophoresis and the gel serially sectioned, frozen and thawed, and extracted with 0·85 per cent sodium chloride. Carbonic anhydrase activity was found only in the region

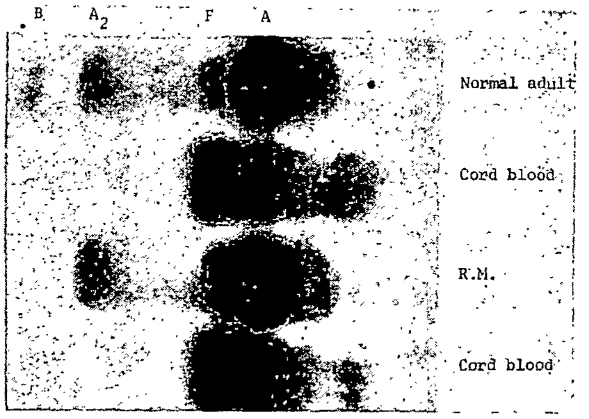

Fig. 1. Vertical descending starch-gel electrophoresis showing marked reduction in carbonic anhydrase *B* from hæmolysates prepared from the blood of R. M. and a normal umbilical cord blood (amido black stain)

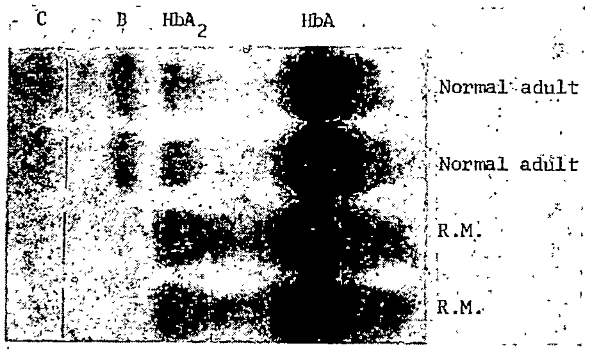

Fig. 2. Vertical descending starch-gel electrophoresis of hæmolysates prepared from the blood of R. M. and a normal individual showing marked reduction in the amount of zone *B* and normal amount of zone *C*, migrating behind the origin (amido black stain)

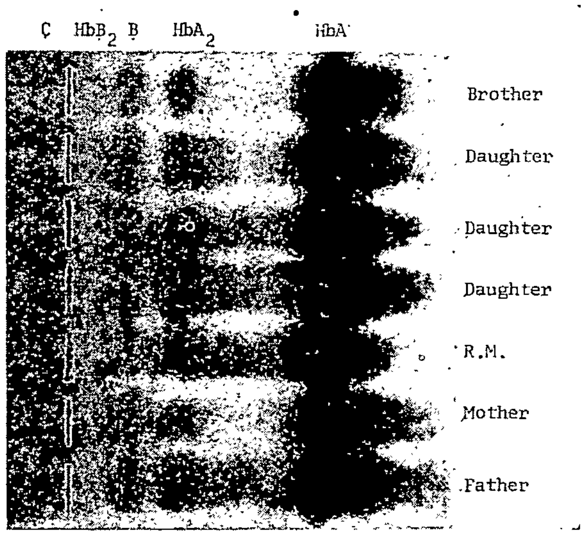

Fig. 4. Vertical descending starch-gel electrophoresis of hæmolysates prepared from the blood of R. M.'s near relatives. In each case carbonic anhydrase zones *B* and *C* are normal. The sample from R. M.'s mother shows hæmoglobin A$_2$ and B$_2$ (amido black stain)

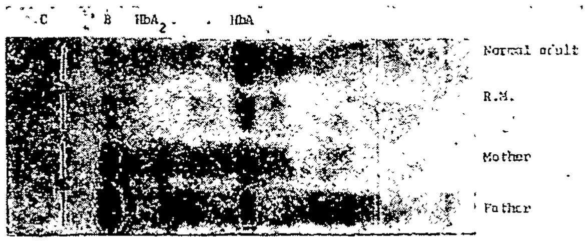

Fig. 5. Non-hæm protein concentrates prepared by 'Amberlite *CG*-50' column chromatography of hæmolysates prepared from the blood of R. M. and relatives (amido black stain)

corresponding to the position of enzyme *C*. In contrast, a normal hæmolysate demonstrated activity in the regions corresponding to the position of *B* and *C*.

The erythrocyte non-hæmoglobin proteins from R. M. and her parents were separated from hæmoglobin by 'Amberlite *CG*-50' column chromatography[14] or by ethanol–chloroform precipitation of hæmoglobin[4]. The non-hæmoglobin protein from each person was concentrated ten-fold by ultrafiltration in 'Cellophane' bags and subjected to starch-gel electrophoresis using both *tris*-EDTA (*p*H 8·8) and phosphate (*p*H 7·0) buffer systems (Fig. 5). No protein band was found in any of these materials that was not present in the concentrated non-hæmoglobin proteins derived from normal hæmolysates. The electrophoretic pattern of the concentrated protein of R. M. did reveal a faint band in the position of enzyme *B*. Serial sections and assays for carbonic anhydrase showed slight activity in the region of *B* in the pattern of R. M. No new region of activity was found for either R. M. or her father. Staining of the gel for esterase activity[15] also failed to reveal a new band of carbonic anhydrase.

Genetically determined variant forms of human erythrocyte carbonic anhydrases[16,17] and baboon erythrocyte carbonic anhydrases[18] have been previously reported. The mutants observed in those investigations showed mobility changes in one of the two enzyme bands. In the work recorded here one band was almost completely absent and no new band was detected. The normal total activity in the red cells of R. M. probably reflects the high activity of the remaining carbonic anhydrase *C* (ref. 4). The genetic relationship of *B* and *C* is not known but they do not appear to be simple chemical derivatives of each other[7]. Isolated complete absence of single proteins has previously been reported for hæmoglobin A$_2$ (ref. 19) and for β$_{2A}$-globulin (ref. 20). In neither instance was an example of inheritance of the trait found. The genetic mechanism of the presently reported variation is not at all clear, but it is possible that R. M. is homozygous for a deficiency in synthesis of carbonic anhydrase *B*. The faint protein band found may represent the minor component of enzyme *C* mentioned by Rickli *et al.*[4], or it may represent a very small amount of enzyme *B*. This situation may therefore be analogous to thalassæmia in that the protein formed is structurally normal but is produced in markedly decreased quantities.

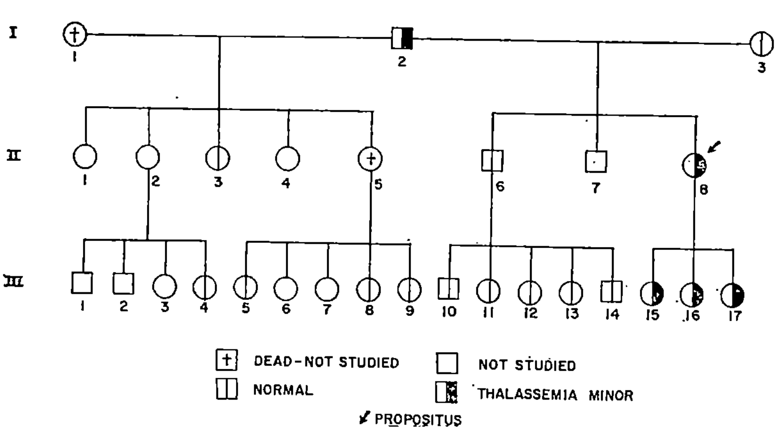

Fig. 3. Family pedigree of R. M. and near relatives

MALARIA ANTIBODY CONTENT OF GAMMA$_2$-7*S* GLOBULIN IN TROPICAL POPULATIONS

By DR. C. C. CURTAIN and DR. C. KIDSON
Baker Medical Research Institute,
Melbourne, Australia*

D. L. CHAMPNESS
Department of Public Health, Port Moresby,
Territory of Papua and New Guinea

AND

DR. J. G. GORMAN
Department of Pathology, Columbia University, New York

A GREAT deal of evidence has been accumulated to demonstrate that the raised γ-globulin levels observed in many tropical populations[1-3] are due in part at least to malarial infection, and it has been shown that species-specific protective antibodies are associated with the γ_2-7*S* globulin fraction of sera from immune adults[4]. It has also been found that malarial infection is associated with non-specific precipitins[5] and complement-fixing antibodies and with the production in rats of auto-antibodies to uninfected erythrocytes[6]. It may also be possible that in the course of the intense activity of the reticulo-endothelial system during malarial infection the production of antibodies to other non-malarial endemic pathogens is enhanced. We have attempted to determine the proportion of the γ_2-7*S* globulin representing parasite antigen-binding antibody in individuals living in holoendemic malarial areas in New Guinea and New Britain.

Two groups of Melanesians living in very different regions, both holoendemic for malaria, were chosen for the work recorded here. One was from the Sause linguistic group in the Sepik River district of New Guinea, the other from the Kilengi linguistic group in the Gloucester Peninsula of New Britain. Anticoagulated whole blood was obtained sterilely from individuals (mostly children) with parasite counts (*P. vivax* and *P. falciparum*) exceeding 10^5/mm^3 and flown, packed in ice, to Melbourne, where cells were separated from plasma by centrifugation and washed three times with 0·9 per cent sodium chloride. The packed cell suspensions were pooled and subjected to sonic disintegration at 20 kc/s for 20 min at 4° C. The resulting mixture was dialysed against 0·1 M sodium borate, *p*H 8·3 and then conjugated to azo-benzyl-'Sephadex *G*200' which had been prepared by the method of Campbell, Leuscher and Lerman[7]. 'Sephadex *G*200' was used instead of cellulose because of its lower non-specific adsorption. The conjugated column material was washed six times by decantation with 0·9 per cent NaCl and packed with stirring[8] into 36 cm × 0·9 cm columns.

The sera to be tested were applied in 1-ml. aliquots to the top of the columns and eluted with 0·9 per cent sodium chloride using the precautions usual to conventional gel-filtration[8]. The progress of elution was followed with a 2570 Å ultra-violet recording photometer. Parallel experiments were carried out using columns prepared with unparasitized erythrocytes. All the column effluents were concentrated to 1 ml. using dry 5 per cent cross-linked acrylamide sticks[9]. These and the original sera were then examined for the presence of malaria antibody by an indirect fluorescent antibody test[10] using acid-washed parasitized blood films, obtained from both children and adults in various areas of New Guinea to ensure a range of parasite species and strains. It was found that a single passage through a column of the specified dimensions, prepared with parasitized erythrocytes, of serum containing malaria antibody detectable by this test was sufficient to remove all that antibody. No discernible change in malaria antibody content occurred after passage of such sera through a column prepared with non-parasitized erythrocytes.

The γ_2-7*S* globulin content of each serum sample, before and after passage through the column, was then measured using a highly specific rabbit antibody[11] calibrated with ^{131}Iγ_2-7*S* globulin using carrier-free isotope and a low level of iodination[12]. The γ_2-7*S* globulin content of an aliquot of each serum sample before passage through the column was also estimated in this way. The proportion of the total γ_2-7*S* globulin represented by malaria antibody is given for different age groups and areas in Table 1.

It can be seen that malarial antibody detectable by the fluorescent antibody technique represents quite a small proportion of the total γ_2-7*S* globulin (6–11 per cent) although it may well be large in relation to the amount formed as specific antibody against other individual types of pathogens. The rise in γ_2-7*S* globulin with age shown in Table 1 is in accord with the age-dependence of γ-globulin levels in New Guinea populations[11]. Thus it appears that the amount of γ_2-7*S* globulin synthesized as malaria antibody remains fairly constant while the total γ-globulin rises with increasing age.

The adsorption of γ_2-7*S* globulin to the columns prepared from the control, non-parasitized erythrocytes was low—0·5 per cent of the total—and there was no increase in adsorption with increasing age of subjects whose

Table 1. MALARIA ANTIBODY AND γ_2-7*S* GLOBULIN

District	Age	Total γ_2–7*S* globulin (g/100 ml.)	Malaria antibody γ_2-7*S* globulin (g/100 ml.)	No. of subjects
New Britain (Kilengi linguistic group)	0–5	1·86 (0·36)	0·21 (0·07)	18
	5–10	2·07 (0·27)	0·23 (0·09)	21
	10–	2·69 (0·21)	0·29 (0·11)	21
Sepik (Sause linguistic group)	0–5	1·79 (0·29)	0·17 (0·06)	26
	5–10	2·11 (0·18)	0·21 (0·12)	12

sera were tested. On this basis, then, antibodies to blood cells do not represent a large part of the very high concentrations of γ_2-7S globulin found in people living in holoendemic malarial areas of New Guinea. This is in contrast to the greater production of anti-erythrocyte antibodies in the rat[6].

In our detailed analyses of serum protein characteristics of Melanesian people in New Guinea[13] we have concluded that the high γ-globulin levels observed are mainly the result of infections. Data accruing from comparisons of children with high and low rates of malarial infection, with respect to globulin-levels and levels of malarial antibody[14], suggest that malaria may play a relatively minor part and that the total infective load may be more important in the ætiology of the hypergammaglobulinæmia. This conclusion is supported by the present quantitative data demonstrating the small contribution of malarial antibody to total γ_2-7S globulin and the absence of increase in malarial antibody γ_2-7S globulin with increasing age. It is in contrast to the conclusions drawn by other workers whose observations have been made in Africa[1-3].

It is possible that the intense activity of the reticuloendothelial system in response to infections results in the production of 'non-specific' γ-globulin, including antibody directed towards autologous tissue determinants. In respect of this possibility it is interesting that we have observed in several New Guinea populations a high proportion of hypergammaglobulinæmic individuals with human tissue antibodies[15], while at least one group (the Tolai in New Britain) exhibit a high incidence (10 per cent) of cold hæmagglutinins[16]. The possibility that the production of auto-antibodies may be one result of high rates of γ-globulin synthesis in tropical populations is worthy of further investigation.

SIMULTANEOUS RECORDING OF ELECTRICAL AND MECHANICAL ACTIVITY OF THE UTERUS IN THE UNANÆSTHETIZED ANIMAL

By Dr. PAUL BASS and MERRITT R. CALLANTINE

Parke, Davis Research Laboratories, Ann Arbor, Michigan

EXTENSIVE research has been devoted to elucidating the mechanisms involved in smooth muscle function[1]. Most of this work has been carried out under *in vitro* conditions. The results obtained in such investigations have led to a variety of hypotheses which are often extrapolated to explain the physiology of the tissue in its *milieu interieur*. In order to aid in testing and integrating the various hypotheses resulting from *in vitro* investigations, it is desirable to perform *in vivo* investigations, provided the latter can be carried out without distorting the normal function of the organ.

This article concerns a method of recording electrical and mechanical activity from the myometrium in the unanæsthetized dog. The method was adapted from investigations performed on the gastro-intestinal tract[2-4]. The animal is prepared for chronic examination by implanting strain gauges and electrodes on the surface of the uterus and exteriorizing the wires to an electrical (female) connector which is sutured to the ventral surface of the abdomen. These animals may be monitored for several hours on a given day and have remained useful for up to four months without impairment of the blood supply, function, or continuity of the uterus. Thus, uterine activity may be recorded in the same animal under a variety of experimental conditions.

The combination electrode-transducer unit used in these investigations is illustrated in Fig. 1. The lower right portion of this figure shows a connecting wire soldered to a platinum electrode which is mounted on the underside of a copper beryllium clip, while the middle portion illustrates the strain gauge mounted on the upper surface of the same clip. In preparing these units, the electrode is placed in a groove in the bottom of a rectangular mould. The assembled strain gauge is then centred over the electrode and insulated from the electrode by a layer of silicone rubber (Medical 'Silastic 372', Dow Corning Corp., Midland, Michigan). The entire unit is then covered with 'Silastic' with the exception of the bottom surface of the electrode. The upper drawing indicates the final size and encapsulation of the electrode-transducer unit. Two or more units may be implanted on each uterine horn of a given animal. Individual electrodes[2] and transducers[3] have also been used successfully to record myometrial activity from both pregnant and non-pregnant dogs and rabbits for prolonged periods of time. The recordings were made on an 8-channel 'Offner' (Type *R*) recorder. A time-constant of 0·03 sec was used to record the electrical activity.

While evaluating the effect of various agents on the myometrium, it was necessary to test a variety of suspending vehicles. Fig. 2 illustrates various types of myometrial

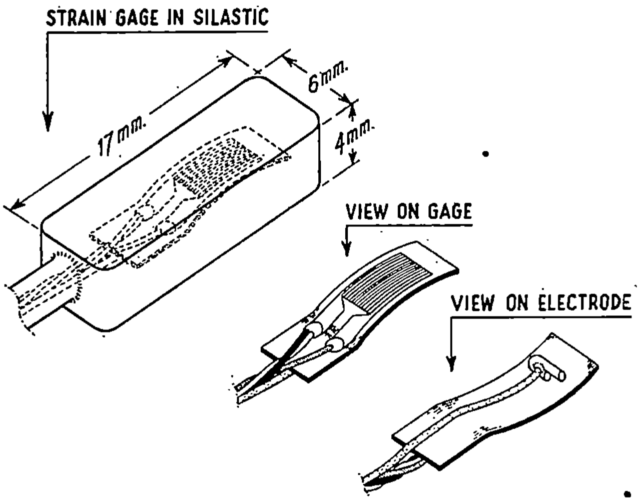

Fig. 1. Combination electrode-transducer unit for recording myometrial activity

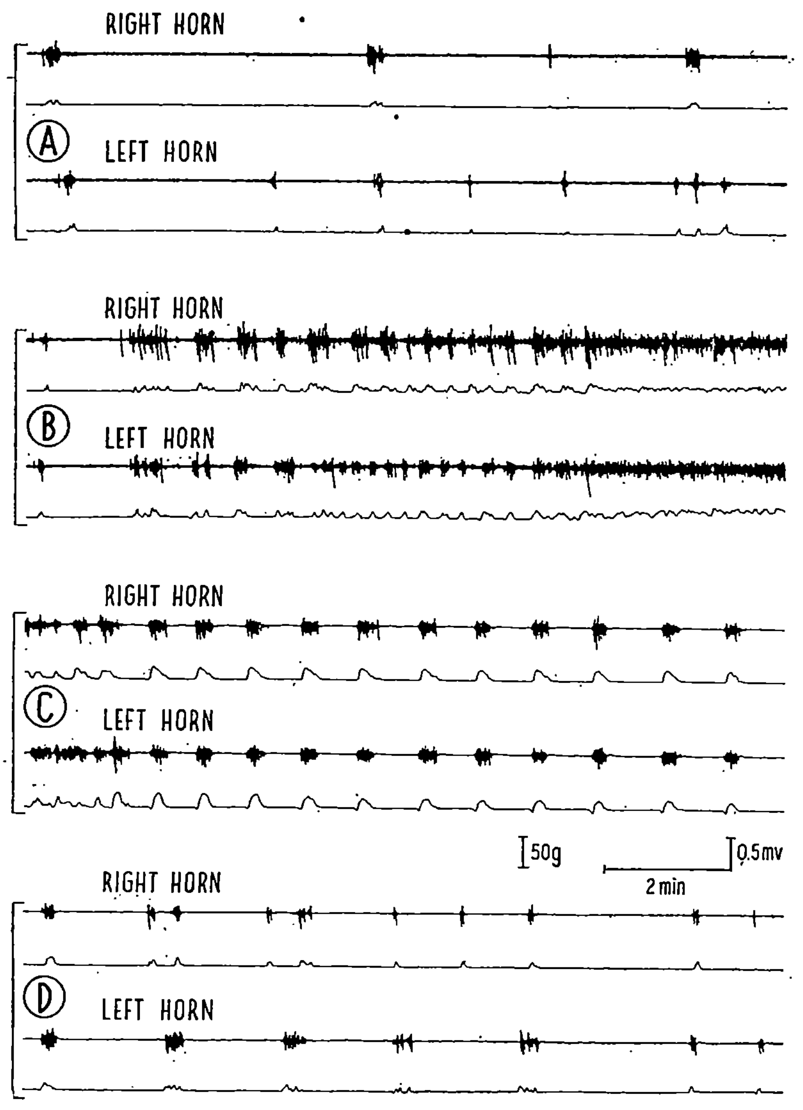

Fig. 2. Effects of a suspending vehicle on electrical and mechanical activity of the uterus of the unanæsthetized dog; mv, mV; g, grams of tension

activity recorded when an aqueous suspending medium was infused into the radial vein of œstrogen-primed dogs. A pellet of 17β-œstradiol (10 μg/kg) was implanted subcutaneously at surgery. The suspending vehicle consisted of sodium chloride (0·9 per cent), polysorbate-80 (0·4 per cent), carboxymethylcellulose (0·5 per cent), and benzyl alcohol (0·9 per cent)[5]. Records similar to that shown in Fig. 2 were observed repeatedly in a total of nine dogs. Record *A* (Fig. 2) shows a control pattern prior to infusion of the above vehicle. The electrical activity of each uterine horn was observed to precede the corresponding mechanical activity of that horn. In addition, myometrial activity of a given horn was independent of the other horn, although occasionally the two horns were synchronized. In general, the frequency and amplitude of uterine activity were related to the level of exogenous œstrogen administered. In this series, the average frequency of uterine contractions was once every 50 sec (record *A*, Fig. 2).

Record *B* (Fig. 2) was recorded within seconds following the beginning of vehicle infusion (1·2 ml./min). It is apparent that both the electrical and mechanical activity of each horn increased dramatically during the first few minutes of infusion. Infusion of the vehicle progressively caused a more asynchronous pattern than was observed during the control period. In addition, the mechanical activity recorded from both horns was observed to go into contracture which was accompanied by excessive depolarization. This contracture normally lasted approximately 6 min.

Record *C* (Fig. 2) illustrates the pattern of myometrial activity obtained after 40 min of continuous infusion of the aqueous suspending medium. In contrast to record *B*, the electrical and mechanical activity of each horn became synchronous. This contractile pattern is similar to, but not identical with, that observed during parturition in the dog. It is obvious that the frequency of the bursts of action potentials and also the magnitude (amplitude and duration) of mechanical activity was greater than during the control period. Moreover, record *C* emphasizes the correlation observed between the electrical and mechanical activity of the myometrium. The contracture pattern (record *B*) was always followed by the synchronous activity (record *C*) whether the infusion of the vehicle was stopped during the contracture or allowed to continue.

Record *D* (Fig. 2) illustrates the return to a pattern similar to the control 18 min after infusion of the vehicle was stopped. The myometrial activity of the two horns has again become more or less asynchronous and the magnitude of both the electrical and mechanical activity has decreased.

The effect of the above suspending vehicle on the electrical and mechanical activity of the myometrium of the unanæsthetized dog was selected to illustrate a variety of uterine contractile patterns. Most of these patterns have been observed in various physiological states in the dog. The contracture and excessive depolarization shown in record *B* (Fig. 2) have been observed with oxytocin. Although no behavioural or nociceptive responses were observed during infusion of the vehicle, this agent was toxic to the animal. Repeated infusion of the vehicle eventually caused considerable hæmorrhage of the lungs and hypertrophy of the kidneys.

The foregoing method of recording uterine activity has several advantages, which include: (1) the preparation is physiological; (2) recordings can be made in the same animal under a variety of conditions over a prolonged period of time; (3) activity is recorded from a localized area of the uterus; (4) the method is applicable to several species. These advantages provide a useful approach to the elucidation of physiological mechanisms.

Electrical activity of the uterus has previously been recorded *in vivo* in the cat[6], rabbit and man[7]. In the latter investigation, Csapo and Takeda also recorded intraluminal pressure of the uterus by means of a small balloon attached to a catheter. The balloon technique records the net pressures within a hollow organ in contrast to our technique which records the tension exerted by the muscle in a localized area. However, both methods of recording are useful in determining and evaluating uterine activity.

PHYSICS

Effect of Gas Flow on the Properties of a Plasma Column

THIS communication describes some effects of gas flow on the properties of a weakly ionized d.c. discharge in argon at pressures of 2–30 mm mercury, with discharge currents of 15–200 m.amp, and gas flow velocities ranging from zero to $1\cdot5 \times 10^4$ cm/sec, corresponding to a Mach number approximately 0·5.

Fig. 1 is a schematic drawing of our apparatus. The discharge is maintained between a hot oxide-impregnated cathode (C) and anode (A). Both electrodes can emit thermionically and thus the roles of cathode and anode can be interchanged. Langmuir probes inserted in the plasma column are used in the investigation of its electrical properties. The static gas pressure is measured at a point midway between the two probes.

Fig. 2 shows the characteristics of the plasma column in the absence of gas flow for a fixed current of 100 m.amp. The electric field E is obtained from the potential difference between the two Langmuir probes of Fig. 1; the electron density N is determined from the ion saturation current drawn to one of the probes when it is biased negatively relative to the plasma potential; and the electron temperature T is obtained from measurements of microwave bremsstrahlung from the plasma.

In Fig. 3 the axial electric field is shown as a function of gas flow at a constant current and pressure. As the flow velocity is increased from zero, E decreases at first, then remains almost constant and rises sharply at a certain flow speed. This speed is independent of the direction of the flow and discharge current, and is inversely proportional to the gas pressure. The corresponding Reynolds number (based on a tube diameter equal to 0·6 cm) is approximately 1,800, a value that is consistent with the critical value for the onset of turbulence in neutral gas flow in a tube. The sharp upward break in E appears to be of the same origin as that observed by Cottingham and Buchsbaum[1] in their investigation of the effect of turbulence on the r.f. breakdown of gases. The reason for the initial decrease in E (indicating an increase in electrical conductivity) is not understood.

It is seen from Fig. 3 that the value of the electric field depends on the direction of flow, at least at low values of discharge current, in our case less than approximately 100 m.amp. This effect appears to be intimately related to the influence of the flow on the travelling striations in the discharge. As many investigators have observed in discharges formed in non-flowing gases, the most intense and commonly observed moving striations (henceforth referrred to as P-waves) are those travelling from anode to cathode. The reported wave-velocities of the striations lie between 10^3 and 10^5 cm/sec, with wave-lengths typically of the order of several tube diameters.

In our experiments the strongest influence of flow is obtained when its direction is from cathode to anode, that is, in opposition to the direction of the P-waves. In fact, at a definite flow speed that depends on the pressure but only weakly on current, the plasma column breaks up into stationary striations (striation spacings $\sim 1\cdot5$ cm). For example, at pressures of 2 and 12 mm mercury and discharge current of 100 m.amp, these flow speeds are $1\cdot9 \times 10^4$ and $0\cdot32 \times 10^4$ cm/sec, respectively. These values are in good agreement with the speeds of P-waves measured[2,3] in non-flowing gases under similar conditions of discharge current, gas pressure and tube radius. They are also in fair agreement with proposed[4] empirical formulæ for P-wave velocities. It appears, therefore, that the stationary striated state of the plasma column occurs when the flow velocity is equal and opposite to the P-wave velocity, at which point the P-wave is effectively brought to rest with respect to the discharge tube.

The audio noise spectrum of the discharge is also influenced by the flow. When the flow is directed toward the cathode, the noise on the Langmuir probes is essentially 'white' for frequencies between 0·5 and 30 kc/s and decreases monotonically with increasing frequency. When the flow direction is toward the anode, however, the signal is periodic with characteristic frequencies of 0·8–2 kc/s, the frequency depending on flow speed, pressure, and current. The amplitudes of the signals range from 1 to 10 V. These effects are observed for gas-flow speeds between approximately 1,000 and 7,000 cm/sec. In this range the average electron density also exhibits a marked increase (as much as a factor of two) and the average electron temperature a 5 15 per cent decrease.

The effects described are influenced only slightly by an axial magnetic field (range, 0–5,000 gauss). Through the

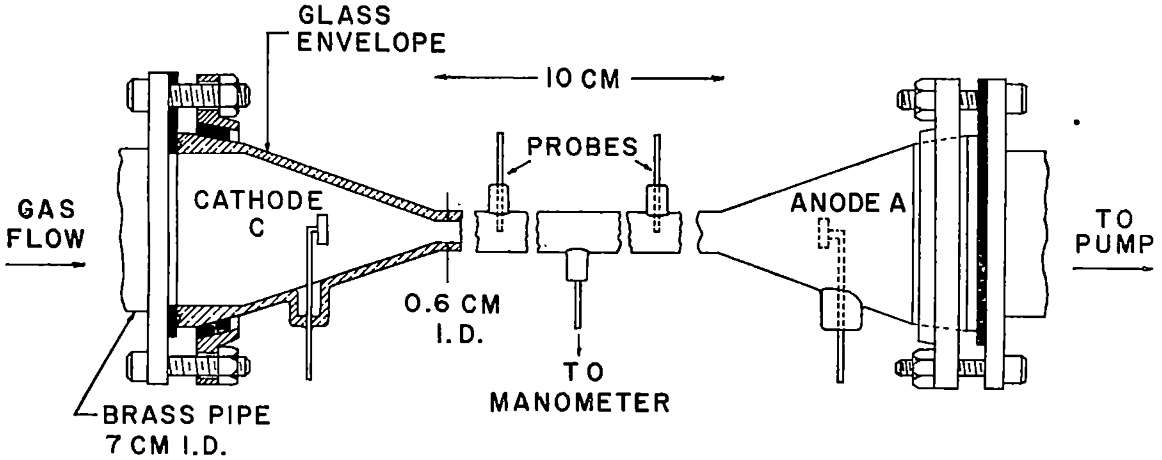

Fig. 1. Experimental arrangement. The role of cathode and anode can be interchanged so that the influence of the direction of the gas flow can be easily studied

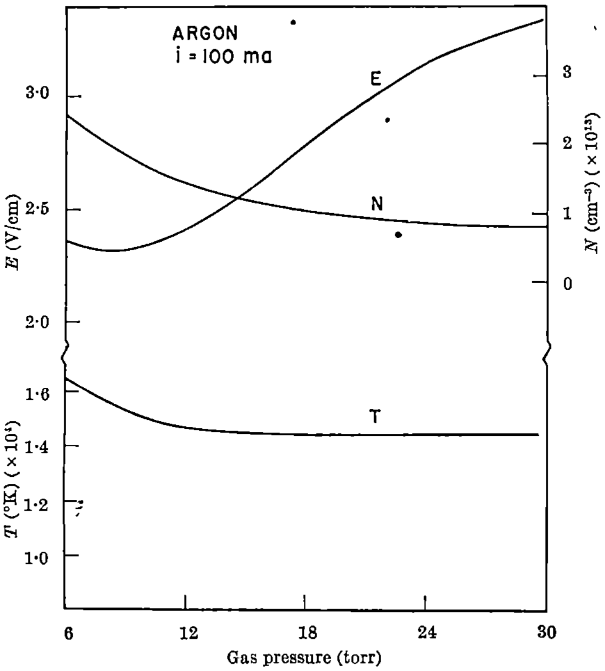

Fig. 2. Discharge characteristics when the flow velocity is zero

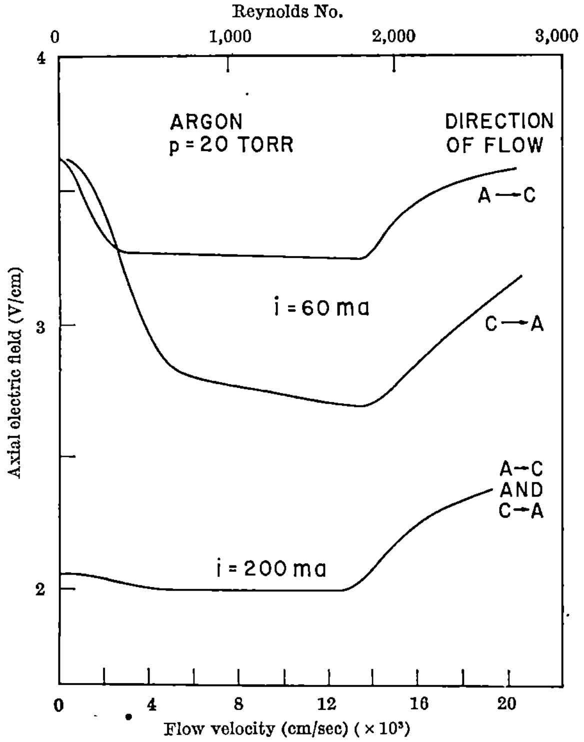

Fig. 3. Influence of gas flow on the axial electric field in the plasma column when the flow is directed from anode to cathode ($A \to C$) and from cathode to anode ($C \to A$)

combined influence of flow and magnetic field, however, a spiral instability can be produced in the plasma column, and at the appropriate flow velocity the plasma spiral can be brought to rest.

Thus, the experiments show that in addition to the expected influence of turbulence on the characteristics of a discharge, gas flow produces more subtle effects that appear to be related to the interaction between the flow and travelling striations and other instabilities in the discharge.

Recognition of Simple Forms

G. E. HAM[1] has examined the hypothetical scanning mechanism of the brain with reference to its expenditure of energy in identifying forms of varying degrees of symmetry. His approach has important implications both for investigations in mental fatigue associated with perceptual tasks (for example, in industry or transport) and also, more fundamentally, for investigations of the seemingly more abstract categorizing processes involved in learning and thinking. Considerations of symmetry have often played a crucial part in the development of scientific and mathematical thought (as conspicuously demonstrated in the recent Ω^- discovery).

But in Ham's treatment there is an implicit model of quasi-mechanical brain-storage of 'sub-shapes' which would be difficult to harmonize with known neurological mechanisms. His general thermodynamic approach would not be invalidated by the adoption of a more plausible model. His storage of sub-shapes does not take account of the possibility of coding, though the coding theorem itself should clearly be related to his thermodynamic concept of form-recognition. This theorem as stated, for example, by Khinchin[2] defines the "compression coefficient μ" for all possible codes thus: "If the entropy of the given text is H, then the greatest lower bound of the compression coefficient μ for all possible codes is H/lg *m*, where *m* is the number of different symbols in the text".

Ham's treatment implicitly postulates an 'inner eye' which visually compares a perceptual image with a stored sub-image, scanning the store to find the best approximation. This must lead to an infinite regress of scanning-mechanisms, the same fallacy as that of the genetic 'homunculus'. It assumes that a visual form can be identified only by comparison with a second visual form. This assumption is neither warranted nor needed. There is certainly no introspective evidence to require it or to support it. Recognition has a quality of immediacy. There is no awareness of scanning or comparison. If we may take it that the 'stored sub-shapes' are completely unconscious they need not be regarded as 'shapes' at all in any visual sense, but rather as distributions of modifications in the brain tissue. As distributions they have spatial extent and pattern but need not have any geometrical isomorphism with visual shapes. They may be as different from a visual shape as a photographed spectrum is from an observed colour, but having an inverse ratio of complexity. Visible colour may be regarded as the brain's coding of the physical spectrum, and, by the economy of the code, contains considerably less information than the physical spectrum. Storage represents a second coding, back into a physical state but with still further economy of information. (We call the intermediate visual experience 'psychological', but it, too, has its physical distribution of neural excitation.)

Thus perceptual coding and memory coding represent two processes of economizing information. The second will be based on certain parameters of the first. The neural excitation involved in perception constitutes a 'pulse-spectrum'[3] and the storage is an abstract of this spectrum. In this interpretation Ham's implicit model of internal quasi-visual comparison is replaced by a process of resonance[4] between parameters of the pulse-spectrum responsible for perception and corresponding spectral features in the stored system of brain-modifications. Owing to the rapidity of resonance (requiring only the time for neural impulses to travel across the brain from the visual cortex to the region responsible for storage) the recognition has a conscious quality of immediacy.

Group-theory provides an invaluable instrument for classifying the parameters for such features as symmetry in the perceptual image, thus providing a measure of information. Tachistoscopic experiments on the immediacy of recognition of forms having different degrees of symmetry could test the coding theorem as applied to compression of perceptual parameters into the code of storage. The very short time-factor would be a measure of the energy involved in the resonance-process. The code, however, may prove more difficult to 'crack' than a simple geometrical analysis suggests. For perceptual recognition depends on more than the focal image. It invokes numerous marginal cues, all of which provide parameters important in producing specificity of resonance. There is always a certain urgency in perceptual recognition and this indicates a thermodynamic factor in the implicit strategy of coding. It will be governed by a law of least action.

[4] Brain, Sir Russell, *Symp. Semantics*, Brit. Assoc. (1955), *Archivum Linguisticum*, 8, Fasc. 1.

THE foregoing comments of Prof. Meredith are most pertinent with respect to suggestions about the particular modes of information storage utilized by the brain. Unfortunately, in trying to explain the thermodynamic approach to recognition of forms in as simple a way as possible I may have left the impression that the brain may actually store 'visual' sub-shapes, as such, for use in comparison with a perceptual image for recognition of the parent shape. Certainly, this implication was not intended. The possibilities for coding of information for use in memory and decision-making have been previously considered by me[1] and are pertinent to the present subject.

Prof. Meredith states that, "There is always a certain urgency in perceptual recognition and this indicates a thermodynamic factor in the implicit strategy of coding". Certainly, this statement is not contested and proceeds directly from my papers. High-speed memory devices have already demonstrated the practicality of immediacy in information storage and retrieval. His suggestion that tachistoscopic experiments could test these conclusions concerning symmetry and immediacy of form recognition is certainly worth while.

In my previous communication I observed that, in its most primitive operation, the brain recognizes simple forms with increasing difficulty. First, as the number of required rotational operations increases and, secondly, as the maximum angle of each rotation increases for superimposition of observed sub-shape and stored parent shape. Using conventional thermodynamic symbols (since we are here dealing with actual energy changes), as we proceed from a rotational requirement of zero for a sphere to two rotational requirements of $\leqslant 180°$ and $\leqslant 180°$ for the most simple of the more complex shapes, we have traversed entropy increases from Δs_1 (equivalent to the entropy change required for recognizing a sphere) to ΔS_s, the incremental entropy increase involved in the recognition of the simplest of the more complex shapes.

Such behaviour suggests a simple relationship between entropy and rotational requirements:

$$\Delta S = \Delta s_1 + \Delta s_2 + R\Delta s_a \qquad (1)$$

where ΔS is the entropy change in recognizing any simple form, Δs_1 has already been defined, Δs_2 is the entropy change associated with invoking a second rotational requirement, R is the sum of the individual maximum angular rotations required, measured in degrees, and Δs_a is the entropy change per degree of rotation. ΔS is, of course, a measure of the difficulty of form recognition.

The equation relating entropy and probability[2] is:

$$S = k \ln W \qquad (2)$$

where S is the entropy of a system; W, the thermodynamic probability, and k, the Boltzman constant. The thermodynamic probability is defined as the ratio of the probability of an actual state to one of complete order.

It seems likely that the relative time required for recognition of a simple object or shape is directly related to W, the thermodynamic probability. In other words, the more probable it is that a form will be readily recognized after a requisite number of 'trials' the shorter the recognition time. Accordingly, the following equation for perception of simple forms is offered:

$$S = k \ln \frac{T_2}{T_1} \qquad (3)$$

where T_2 is time to recognition of a given simple shape and T_1 is time to recognition of a sphere. It is noted that if a sphere is being observed, the equation reduces to $S = 0$. Of course, the equation is limited to entropy changes in excess of those for recognition of a sphere, hence Δs_1 must be added. In addition, the upper limit of equation (3) would be determined by the time required to recognize the most complex shape with which the brain is acquainted. The upper limit of equation (1) is $\Delta S_s + \Delta S_1$, the entropy change involved in the recognition of the simplest of the more complex shapes.

Experimental confirmation of the foregoing equations offers some problems. However, since:

$$\Delta S = \frac{\Delta H}{T}$$

where ΔH = the change in heat content in a given transformation, and T is the absolute temperature, measurement of the change in heat content of the appropriate brain region involved during recognition is suggested.

It seems likely that the brain scans stored 'sub-shapes' in sequence according to increasing complexity. Such a result would be consistent with the foregoing treatment, as well as with introspective conclusions about the nature of symmetry.

Optical Correction in Micro-electrophoresis

AN optical correction in the microscopic measurement of the electrophoretic mobility of particles was proposed by Henry[1] and has been discussed more recently by Hunter and Alexander[2]. The correction concerns measurements made in the type of cell similar to that used by Mattson[3]. Such cells consist essentially of a thick-walled capillary, the outer face of which is ground flat to within a short distance of the inner bore. The foregoing authors discussed the apparent position of a point within the cell resulting from refraction through the circular cell wall.

However, these authors did not make it clear that the optical system presented by cells of this type show a complex form of astigmatism[4]. A point within the cell gives rise to two virtual images, both of which are in the form of caustic surfaces, having cuspidal edges. These edges, which are mutually perpendicular and non-intersecting, may be the only parts of the image which are visible in practice. When the aperture of the microscope is small, the length of the edges may be sufficiently short for a point image to be observed when the microscope is focused on any point between them. The results of astigmatism, therefore, may appear only as a lengthening of the depth of field of an observed image.

Let us consider an emitting point source at a depth d from the inner wall of the cell of radius a. Suppose the refractive indices of the immersion medium, the cell and the dispersion medium are n_1, n_2 and n_3 respectively. The depth $d_1^{\text{app.}}$ of one caustic edge is given by :

$$d_1^{\text{app.}} = \frac{n_1 d}{n_3 + \dfrac{d}{a}(n_2 - n_3)} \qquad (1)$$

while the position of the other is obtained by putting $a = \infty$, that is,

$$d_2^{\text{app.}} = \frac{n_1 d}{n_3} \qquad (2)$$

The depth of field resulting from this effect is therefore :

$$d_2^{\text{app.}} - d_1^{\text{app.}} = \frac{\dfrac{d}{a}(n_2 - n_3)}{n_3 + \dfrac{d}{a}(n_2 - n_3)} \qquad (3)$$

This field-depth depends not only on the radius of the cell but greatly increases with the depth within the cell of the observed point. For example, when $n_1 = n_3 = 1{\cdot}33$, $n_2 = 1{\cdot}51$, $\dfrac{d}{a} = 0{\cdot}293$ (near stationary layer) and $a = 1{\cdot}0$ mm, the length of the image along the microscope axis is 11μ. However, the image of the far wall of such a cell would have a length of 430μ.

The formulæ presented by Henry, and also Hunter and Alexander, relate to only one of the caustic edges, namely, that which is a function of the cell radius. The burden of Henry's argument was that it is not possible to select a given level in the cell by linear interpolation between the apparent positions of the near and far walls.

When the system's astigmatism is considered, it is evident that while one can focus with reasonable accuracy on the apparent position of a point at the near stationary layer, it is usually quite impracticable to focus on the far wall of the cell. There appears to be no valid circumstance, therefore, where the Henry correction could be applied.

If a microscope objective has a sufficiently large numerical aperture to enable the caustic elements to be seen as edges, it should be possible to choose the edge which conforms to equation (2). A given level would then be found by linear interpolation. Where this is not possible, it seems essential to measure the cell bore by an alternative method and apply a simple refractive index correction, where necessary.

Moving Helium Film Measurements

Measurements on the profile of the moving helium film by Gribbon and Jackson[1] have given qualitative, but not quantitative, support to Kontorovich's theory[2] of the moving film. This theory was based on the postulates of the two-fluid model of liquid helium, and it predicted that the moving film would be thinner than the static film, while an alternative theory by Franchetti[3] predicted a thicker moving film. Tilley[4] has reconciled the two approaches using arguments based on the thermodynamics of a system in which relative motion occurs and has confirmed Kontorovich's result. Recently Franchetti[5] has proposed several reasons for the contradiction between the measurements and the simple theory.

Franchetti has suggested that disturbances, such as evaporation, were present which altered the expected magnitude of the change in thickness of the film as it flows out of a beaker. Now if it is accepted that there are two competing processes which could affect the film thickness, then a superfluid flow process could decrease, and a downward temperature gradient[3] could increase, the film thickness. The latter effect is negligible in a film at a typical temperature not too close to the λ-point, and superfluid flow alone need be considered. The film would be disturbed if evaporation took place above or at the measuring region on the outer wall of the beaker. Evaporation would occur if there were an unbalanced heat input to the film from either thermal vibrations in the helium vapour[6], absorption of thermal radiation from the cryostat surroundings[7], or absorption of incident radiation from the sodium lamp source[8] used in the optical method of film thickness measurement. There was no evidence for a heat input due to thermal vibration while the estimated heat input from thermal radiation was at least an order of magnitude less than the maximum heat input of about $100\ \mu\text{W cm}^{-2}$ from the absorbed sodium lamp radiation[9,10]. However, since the influence of evaporation applied equally to both the moving and the static film, measurements made to find the difference in thickness between these films would be independent of any thickness change due to evaporation. Since in practice this was the experimental technique used, the contradiction between experiment and theory is not resolved by taking account of any evaporation.

Secondly, Franchetti has pointed out that the theory only applied to a reversibly flowing film and is not strictly applicable to an irreversible film transferring out of a beaker. However, when the initial high transfer rate had decreased to the more characteristic rate, local equilibrium should have been reached in the measuring region and the theory should hold. The thickness measurements were made under these conditions, the film flowing at the steady characteristic rate of about 12×10^{-5} cm^3 cm^{-1} sec^{-1} and the measurements being taken well below the irreversible region close to the beaker rim[3,11].

Finally, Franchetti suggested that the film flow also would be irreversible if vorticity were present. Allen[12] and Kuper[13] considered that an array of vortex lines in the film might be responsible for the fast flow rates found under certain conditions ; but recent work[14] has shown that these enhanced flow rates seem more likely to be due to the presence of an unstable thick film draining slowly to the normal film thickness on the inner surface of the beaker. Nevertheless if a regular array of rolling vortex lines were present the thermodynamic free energy and hence the film thickness would be altered, but the contribution of this additional vorticity free energy would be negligible compared with the superfluid kinetic energy contribution. A further small free-energy contribution might arise due to the absorption of radiation energy by the beaker surface with subsequent heat flow into the film producing a turbulence energy density in the superfluid.

In conclusion it may be said that Franchetti's suggested reasons for the disagreement between the experiments and the theory do not resolve the problem, and indicate that further experimental and theoretical work is required on the moving helium film.

Additional Observations of Probable Stimulated Emission of a Terbium Ion Chelate in a Vinylic Resin Matrix

The experimental results presented here were to have been included as an addition to my first communication[1]. However, the results were not submitted in time to be included in it. I should like at this time to present these additional results, as they provide a more definite indication of probable stimulated emission of terbium thenoyltrifluoroacetonate Tb(TTA) in a polymethyl-methacrylate (PMMA) matrix than the results presented in the previous communication[1].

Hereafter, in this communication I shall refer to the Tb(TTA) doped (PMMA) fibres, some of the properties of which were investigated in the experiments presented in my first communication, as belonging to the first group[1]. The fibres investigated, for which the results are presented in this communication, will be referred to as the second group.

These new experimental results are presented in the form of oscilloscope recordings of the fluorescence emission (≈5450 Å) versus time of the second group of fibres. These fibres are of higher optical quality than those of the first group. This second group of fibres is doped with a Tb(TTA) concentration of ≈0·08 per cent of the weight of the PMMA, and have diameters and straight lengths of approximately 0·75 mm and 65·0 mm respectively. The ends of these fibres were polished, but not silvered. The second group of fibres possesses a smaller degree of strain, bubbles, surface voids, and other surface imperfections than the fibres of the first group, because of improved fibre fabrication technique. Other physical parameters of the second group of fibres are essentially the same as those measured for the first group.

The experiments with the second group of fibres were performed with the fibre cooled to 77° K, and with the same experimental apparatus (except for a change in the pump light filter from a Corning 7–54 to a Corning 7–51 filter glass) as was used in the investigation of the first group of fibres[1]. The photomultiplier output load resistor also was changed to a smaller value in order to improve the time resolution of the observation.

The more pronounced spiking, and the suggested lifetime shortening of the fluorescence decay time observed in the second group of fibres as compared to the same characteristics in the first group, I attribute primarily to the improved optical quality of the second group of fibres (Figs. 1–5*b*), which resulted in lower fibre cavity losses, and therefore in a larger degree of spiking of the fluorescence emission. However, the increased time resolution of the photomultiplier is also responsible in part for the difference in the characteristics of the oscilloscope recording between the first and second group of fibres. In these experiments with the second group of fibres, as in the experiments with the first group, blank, undoped fibres of polymethyl-methacrylate were substituted for the Tb(TTA) doped fibres in the experimental apparatus in order to determine the degree of pump light leakage, and to detect if any spurious responses due to unusual pump light output, pump light filter fluorescences, or polymethyl-methacrylate fluorescences occurred. No spurious responses were noted in the oscilloscope recordings for the blank, undoped fibres (Figs. 2*b* and 5*a*), and only a small amount of pump light leakage was observed.

The results represented by Figs. 1–5*b* are for single, Tb(TTA) (≈0·08 per cent of wt. PMMA) doped fibre of the dimensions described here, under the condition of increasing pump power. Observation of several other Tb(TTA)-doped fibres of the second group indicates quite similar behaviour.

Due to the small amount of (≈5450 Å) output power obtainable from both groups of these short fibres of Tb(TTA)-doped polymethyl-methacrylate, it was not possible to observe, with the spectrograph available, whether or not line-narrowing due to stimulated emission occurred. Observation of coherence properties was also thwarted for the same reason. Fibres of longer length needed to provide increased output power necessary to

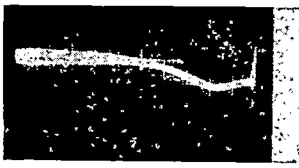

Fig. 1. Near threshold emission at 400 joules input

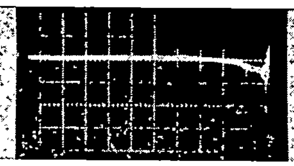

Fig. 5*a*. Blank sample (pump light leakage) at 1,200 joules input

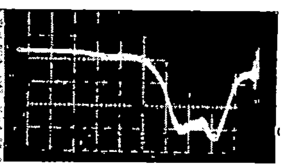

Fig. 5*b*. ≈5450 Å emission at 1,200 joules input

Figs. 1–5*b*. In the Figs. 1–5*b* increasing time is from right to left, and the sweep time 500·0 μsec for all figures. The photomultiplier voltage and anode load resistance are the same for Figs. 1–5*b*. The oscilloscope vertical amplifier sensitivity is the same for all figures, except Fig. 2*c*, which is 100 times less than the sensitivity for all the other figures. The pump light outputs for Figs. 1, 3, 4 are not shown, but are similar in shape to the flash lamp output of Fig. 2*c*. The sharp spikes at the beginning of the trace are due to trigger spike leakage make these observations were not available, because of difficulties encountered in obtaining the necessary optical quality in fibres of greater than approximately 75·0 mm in length.

The increased spiking amplitude to exponential spontaneous emission amplitude ratio, the suggested lifetime shortening, and the indicated spike sharpening under increased pumping as is shown in Figs. 4 and 5*b* are also indications of probable stimulated emission. However, since all proofs are not available at this time, the conclusion must remain that the phenomena observed in these experiments for both groups are only to a moderate degree of probability-stimulated emission.

In conclusion, I wish to note a divergent interpretation of the results presented in my previous communication[1], based on conclusions drawn from observations of the fluorescence emission of other rare earth, beta diketone chelates, in various solutions[2].

ENGINEERING

Stress Concentration in Concrete

In carrying out some experimental work in the torsion of hollow concrete box beams, the authors were surprised to discover that the size of the fillet radius at the internal corners has little or no effect on the strength of the section. That is to say that in practice, although not in theory, there was no measurable stress concentration effect. This point has also been noted by Turner and Davies[1], who tested *T*-beams in torsion with a sharp re-entrant corner.

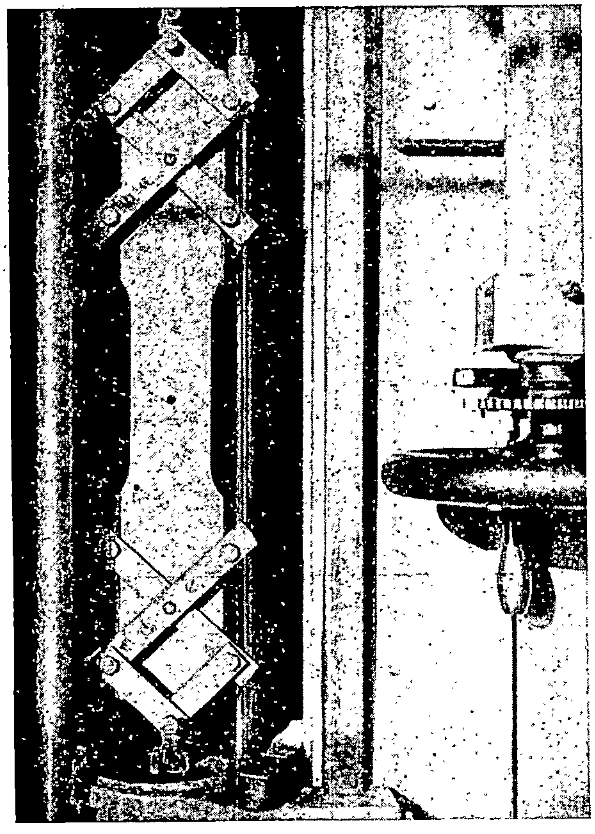

Fig. 1

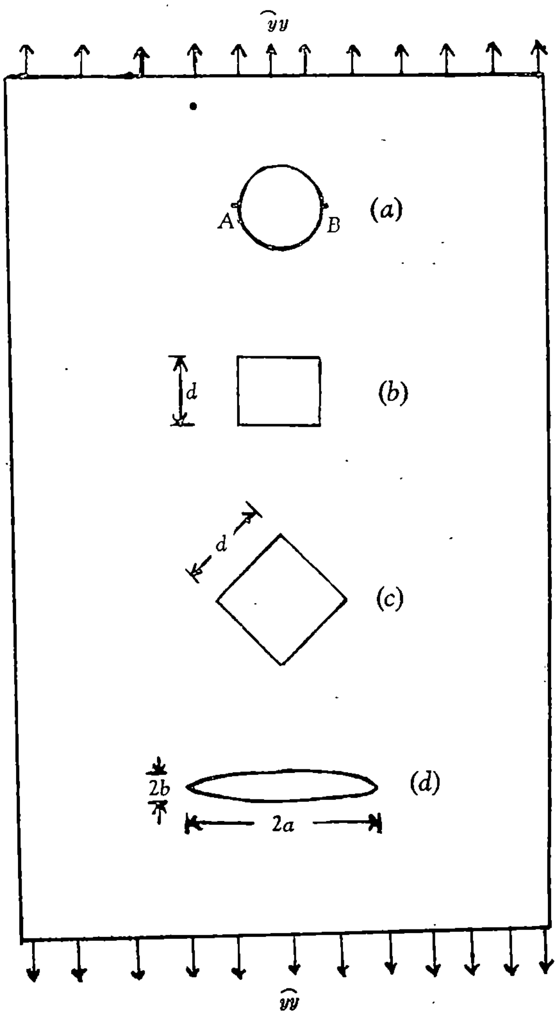

Fig. 2

In an attempt to find an explanation, tensile tests were carried out on plain thin concrete specimens, using a lazy tongs gripping device developed in the Engineering School and described previously elsewhere[2] (Fig. 1). The purpose was to ascertain the effects of holes of various shapes on the tensile strength. Tests were first of all carried out on sections with circular holes (Fig. 2*a*) for which the stress concentration factor is 3, that is, the stress at points *A* and *B* is 3 times the applied stress, that is, $3\widehat{yy}$. Allowance was made for the reduction in area due to the hole and no stress concentration effect was found, that is to say the failure stress was the same as that for a specimen without a hole. A square hole with a corner radius of 0·014*d* was then used (Fig. 2*b*), but again the effect was negligible in spite of the fact that the stress concentration factor as computed by the complex variable method was 5·9. In fact the section with the hole gave slightly higher values for the tensile stress, as one would expect from statistical theory. A diamond hole with a corner radius of 0·014*d* was then resorted to (Fig. 2*c*) and a 10 per cent decrease in strength was found, with a computed stress concentration factor of 14·8. This small decrease could be entirely due to experimental error since only three tensile specimens were used. As there still seemed to be no appreciable effect thin slits were tried; these were meant to simulate ellipses, for which the formula for the stress concentration factor is $\left[1 + \frac{2a}{b}\right]$, where *a* and *b* are the semi-major and semi-minor axes of the ellipse (Fig. 2*d*). The stress concentration factor varied from 40 to 80, but still no effect was noticed. However, the ellipses were not true ones and the stress concentration factor probably mainly depends on the radius of curvature at the end of the major axis, and the radii on the specimens tested could well have belonged to ellipses of smaller a/b ratio. The results for elliptical sections should therefore be treated with some caution, though clearly they confirm the general trend.

The fact that a brittle material like concrete is not reduced in strength by the presence of such high stress concentrations calls for some explanation. A possible hypothesis is to assume that there is a redistribution of stress due to plastic flow as in the case of ductile materials like mild steel. Although this is put forward by Turner and Davies[1] by way of explanation, it is not considered by the authors as very probable because of the peculiar structure of concrete.

Concrete is a macroscopically homogeneous and isotropic material which is full of air and water voids. The latter are usually very small, of spherical shape and closely packed together. The air voids, which are due to incomplete compaction, are of all shapes and sizes. Since concrete is a non-linear visco-elastic material the stress distribution for instantaneous loading follows the elastic theory. The stress concentration factor inherent in concrete due to all the voids, and also the stress concentrations which occur at the interface of the cement and the sand grains, must be of large magnitude. For glass, which seems to have considerably fewer voids than concrete, a stress concentration factor of 600 has been calculated. A. A. Griffith[3] showed that there was an enormous difference between the theoretical molecular strength of glass and the actual tensile strength of ordinary glass. By carefully making some glass rods as free as possible from voids and surface scratches he increased the tensile strength to about half the molecular strength. In glass it seems that the dominant factor is the state of the surface, while in concrete the internal structure is likely to have just as much, if not more, effect. The authors believe that concrete fails at very low loads because the inherent stress concentration factors are very high, much higher than the stress concentration factors artificially introduced in their experiments.

Alternatively, concrete could be regarded as being of honeycomb structure with a very small mesh size, so small that it could not be affected by any artificial stress raiser such as, for example, a hole or sharp change in angle.

CRYSTALLOGRAPHY

Structure of Strontium Caprylate Hydrate

The strontium caprylate was prepared by metathesis from sodium caprylate and strontium chloride. The material crystallized from aqueous solution in the form of very small fragile plates. All the crystals examined were twins and all the X-ray photographs showed streaking of the spots, indicating some disorder in the long axis direction.

The crystals were triclinic with unit cell dimensions a = 4·7 Å, b = 8·0 Å, c = 25·8 Å, α = 94°, β = 91° and γ = 100°. The space group was assumed to be $P\bar{1}$. The position of the strontium atom was determined from the Patterson syntheses of the [100] and [010] projections. Both projections were refined by Fourier and Fourier-difference methods. The final value of the residual, R, was 0·16 for both projections. Because of the twinning the estimates of some of the intensities of some of the reflexions in both zones are uncertain and the structure cannot be regarded as very accurate.

There are some very unusual, non-crystallographic symmetries in the structure. The [100] projection exhibits symmetry about the lines perpendicular to the b axis through the points $\frac{3}{4}$,0, and $\frac{1}{4}$,0. The Fourier transform of the unit cell appears to be symmetrical, or very nearly so, but the reciprocal net is non-orthogonal and so the sampling is not symmetrical. Fig. 1 shows the final Fourier synthesis of the electron density projected along [100] and a diagram of the structure. The accidental symmetry is apparent in Fig. 1.

The [010] projection appears to have the symmetry *pmg*. In this projection not only is the Fourier transform of the unit cell contents symmetrical but also the reciprocal net is orthogonal and the sampling is orthogonal too. This projection showed no difference in intensities between reflexions related by the apparent symmetry in spite of the two halves of the twin being very different in size (as shown by the [100] projection). The projection was therefore refined assuming that the plane group was *pmg*. Fig. 2 shows the electron density projected along [010] and a diagram of the structure.

The structure consists of an ionic layer containing the strontium ions with eight oxygen atoms as nearest neighbours in the form of a distorted octahedron, six from the carboxylic acid groups and two from the water molecules. The hydrocarbon chains are normal to this layer. The

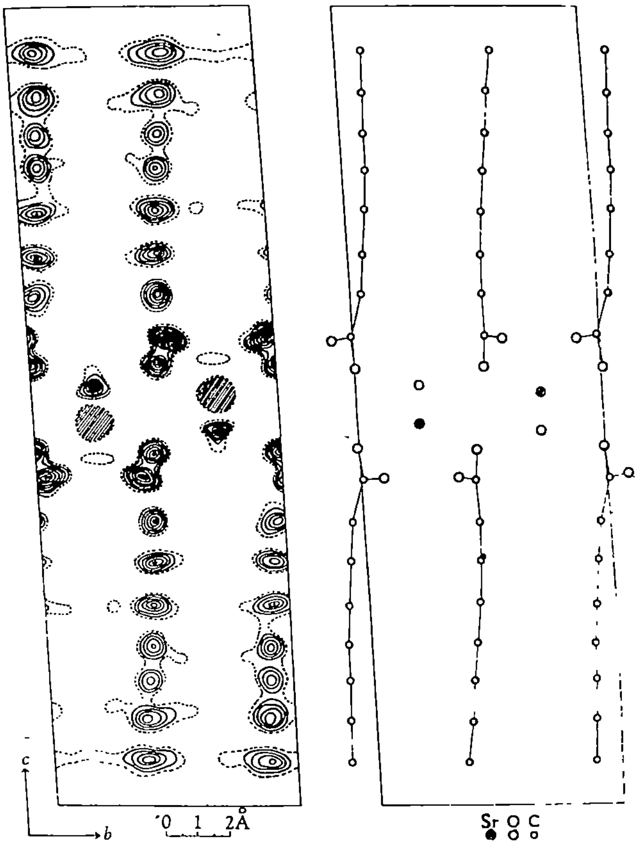

Fig. 1. Left, Fourier synthesis of the electron density projected along [100]. The contours are at intervals of one electron per Å^2. The zero contour is broken. The strontium ion has been shaded. Right, diagram of the structure projected along [100]

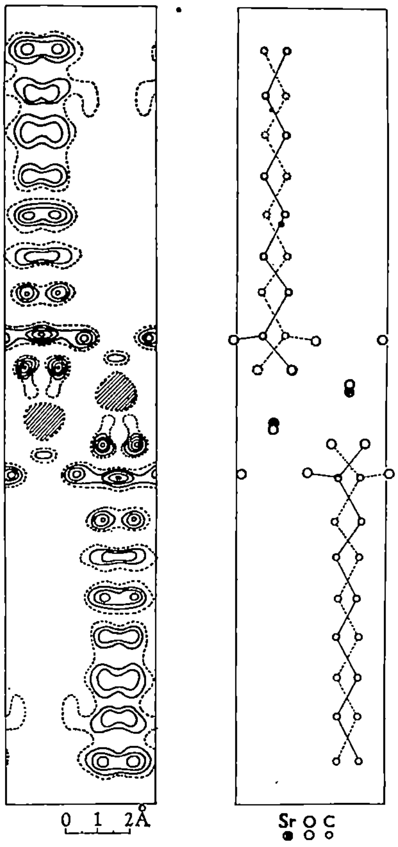

Fig. 2. Left, Fourier synthesis of the electron density projected along [010]. The contours are at intervals of two electrons per Å^2. The zero contour is broken. The strontium ion has been shaded. Right, diagram of the structure projected along [010]

mean Sr—O distance is 2·62 Å, which agrees with the ionic radii. The C—O bonds in the carboxylic acid groups are not of the same length. One is 1·31 ± 0·08 Å, the other is 1·16 ± 0·08 Å. These are of the same order of magnitude as those found by Vand, Morley and Lomer[1] in lauric acid. The mean C—C distance in the hydrocarbon chains is 1·48 ± 8 Å, which is not significantly shorter than the value of 1·51 Å found by Turner and Lingafelter[2] in tetradecamide. The average distance between alternative carbon atoms in the chain is 2·59 ± 0·3 Å, which is the same as that found by Vand, Lomer and Lang[3] in potassium caprate but is longer than the value of 2·53 found by Turner and Lingafelter[2] in tetradecamide. The structure appears to be quite different from that of strontium laurate proposed by Morley and Vand[4].

Calcium Fluoride : Slip and Polygonization during Crystal Growth

Calcium fluoride occurs in Nature as the crystal form known as fluorite. It can, however, be grown artificially as single crystals, and when doped with suitable impurities it is widely used as a laser material[1,2]. For this purpose,

during deformation experiments[5]. After annealing for a period of one week at a temperature of 950° C in an atmosphere of pure argon, the dislocations in the slip bands polygonized to give more low-angle boundaries (Fig. 2); the boundaries formed during growth remain unaltered by this annealing treatment.

Slip bands and low-angle boundary arrays are also observed on Stockbarger-grown crystals (Fig. 3) and the slip vector is again <110>. The number of dislocations and the amount of slip which occurs are, however, far less than in the Czochralski-grown crystals. Typical dislocation densities are respectively ~ 10^5 cm^{-2} and ~ 10^3 cm^{-2} for Czochralski and Stockbarger crystals. Furthermore, the latter crystals show the highly polygonized arrays of Fig. 4 without further annealing.

It is well established in semiconductor materials, such as germanium[7,8], and in laser materials, such as calcium tungstate[9], which have been grown by the Czochralski technique that dislocations are formed as a result of plastic flow which occurs in order to relieve thermal stresses in the cooling material. The evidence presented here suggests that calcium fluoride crystals, grown by the same technique, also fit into this general pattern of behaviour as the slip bands along <110> directions are very similar to those observed on {111} surfaces of germanium and the arrangement of low-angle boundaries is similar to that observed in calcium tungstate crystals[9]. This hypothesis also explains why the dislocation density in crystals grown by the Stockbarger method is much lower than in Czochralski-grown crystals, namely, because of the lower temperature gradients and correspondingly lower stresses experienced in this process. The slow cooling associated with the Stockbarger technique also permits dislocations to move into the observed highly polygonized configurations.

The slip bands observed in calcium fluoride crystals remain unmodified on crossing a low-angle boundary, thus suggesting that the slip occurred after the formation of the boundaries. This behaviour is in contrast to that of calcium tungstate crystals grown by the same method[9] where, although regions of high dislocation density are observed in addition to low-angle boundaries, there is no evidence of massive slip or of slip bands crossing the boundaries. The *a* [100] slip vector for dislocations in calcium tungstate[10] is, however, much larger than the slip vector in calcium fluoride and also involves the movement of the complex $(WO_4)^=$ ion rather than the movement of single ions. It is likely, therefore, that dislocations are more easily generated and moved in the fluorite lattice than in the calcium tungstate (Scheelite) lattice; this could explain the more extensive slip observed in calcium fluoride crystals pulled from the melt. However, as both these materials lose heat during growth by transmitting radiation from the solid/liquid interface along the crystal[11], it is possible that the calcium tungstate crystals will cool more slowly because this material absorbs most of the radiation at wave-lengths greater than 3·6μ whereas calcium fluoride is transparent to radiation at wave-lengths as high as 10μ. As the crucible and melt approximate to a black body and the peak of the black-body radiation curve at the melting-points of these materials is at approximately 2·5μ, it is likely that calcium fluoride absorbs very little radiation whereas approximately 15 per cent could be absorbed by calcium tungstate. The consequent lower cooling rate in the latter case may permit dislocations to start polygonizing, thus masking any slip that has occurred.

The dislocation patterns observed in artificially grown calcium fluoride crystals can thus be explained in terms of the thermal stresses present in the growth process. The differences in the dislocation patterns of calcium fluoride and calcium tungstate can be interpreted in terms of the different crystal structures and transmission properties of these materials.

We thank Dr. W. Bardsley for his advice.

CHEMISTRY

Effect of Micro-crystal Formation on the Electron Spin Resonance Spectra of αα-Diphenyl-β-picrylhydrazyl in Various Frozen Solvents

Despite the very numerous investigations of the electron spin resonance spectra of DPPH (αα-diphenyl-β-picrylhydrazyl) a number of perplexing problems remain. Those relating to its behaviour in various solvents are important because DPPH is used very commonly as a standard for concentration measurements in electron spin resonance and as a radical 'scavenger' in the examination of radiation chemistry.

During an investigation into the suitability of deaerated frozen solutions of DPPH in various solvents as concentration standards at low temperatures[1], it was found that there were wide differences in line width, hyperfine splittings and saturation behaviour, not all of which could be explained. In particular, frozen solutions of DPPH in benzene (10^{-3}–10^{-4} M) gave a strongly exchange-narrowed line about 2 gauss wide, while the very similar solvents, toluene and xylene, gave broad, poorly resolved five-line spectra like broadened versions of the solution spectra.

It was also found that the frozen benzene solutions showed little microwave power saturation, whereas the others all saturated heavily at 77° K. Further investigations showed that the electron spin resonance spectra could be divided into three groups: (*a*) strongly exchange-narrowed (peak to peak line width $\Delta H_{pp} \sim$ 2–4 gauss), for example, benzene, naphthalene, quinoline (Fig. 1*a*); (*b*) broader, unresolved lines ($\Delta H_{pp} \sim$ 10–20 gauss), for example, acetone, diethyl ether, toluene, carbon disulphide, thiopen (Fig. 1*b*); (*c*) poorly resolved five-line spectra with hyperfine splittings greater than those observed in solution, for example, pyridine, tetrahydrofuran, xylene (Fig. 1*c*).

The spectra of group (*c*) are similar to those observed by Schneider[2] for DPPH in solidified 'Perspex' or polystyrene, and by Lord and Blinder[3] for DPPH and carbazyl in a plastic cement. These latter authors show clearly that the increase in hyperfine splittings and line-width is the result of including anisotropic contributions which are averaged out in solution. It has been suggested[4] that the exchange narrowing of the spectra of group (*a*) results from 'super-exchange' throughout the whole lattice or from crystallization of the solute in the form of micro-crystals.

In order to test this suggestion we have examined thin films of frozen solutions on the cold stage of a high-powered polarizing microscope. A concentration of about 10^{-2} M DPPH was needed for proper observation, and at this concentration micro-crystals of DPPH could clearly be seen in frozen benzene by means of their characteristic

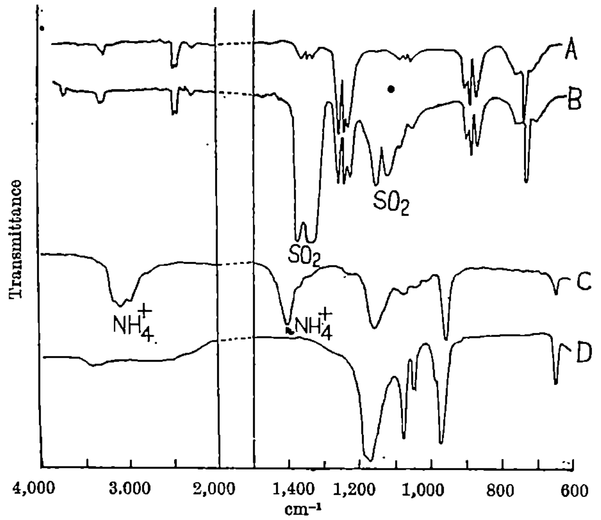

Fig. 1. Infra-red absorption spectra of: (*A*) HNSO; (*B*) gaseous product and (*C*) solid product obtained by reacting ammonia with excess sulphur dioxide; (*D*) $K_2S_2O_5$

under completely anhydrous conditions[6] occurs rapidly with evolution of heat. The infra-red spectrum of the gaseous product was shown to be thionylimide, HNSO[7], and the spectrum of the simultaneously formed solid product showed the presence of NH_4^+, HSO_3^- and $S_2O_5^{2-}$ immediately after the reaction, but the latter gradually changed into $S_2O_5^{2-}$ with the lapse of several hours. The infra-red spectra of this solid indicated no existence of SO_3^{2-}, $S_3O_6^{2-}$, $S_4O_6^{2-}$, etc. (Fig. 1).

$$3NH_3 + 3SO_2 \longrightarrow HNSO + (NH_4)_2S_2O_5$$

The reaction between methylamine and sulphur dioxide (as would be expected, occurrence of a similar reaction in view of the proceeding one) produced methylthionylamine, CH_3NSO, and pyrosulphite, $(CH_3NH_3)_2S_2O_5$. Likewise, the reaction between ethylamine and sulphur dioxide produced ethylthionylamine, C_2H_5NSO, and $(C_2H_5NH_3)_2S_2O_5$.

The reaction between dimethylamine and sulphur dioxide produced almost quantitatively a yellowish oily liquid, which was purified by vacuum distillation without decomposition; m.p. 17° C. The formula was found to be a molecular complex, $(CH_3)_2NH{\cdot}SO_2$, by infra-red and Raman spectra[8] and also by mass spectrum. The strong hydrogen bonding in this molecule did not show a remarkable effect on the absorption band by increasing dilution of non-polar solvents. An extensive examination has been also made on far infra-red and Raman spectra of molecular complexes, $(CH_3)_2NH{\cdot}SO_2$ and $(CH_3)_3N{\cdot}SO_2$. New bands, 205 cm⁻¹ for the former and 186 cm⁻¹ for the latter, could be found as intense Raman line and weak infra-red absorption band also. It may be considered that the bands indicate the bond of $N \cdots S$ caused by charge transfer force.

We thank Prof. R. Hara for his advice.

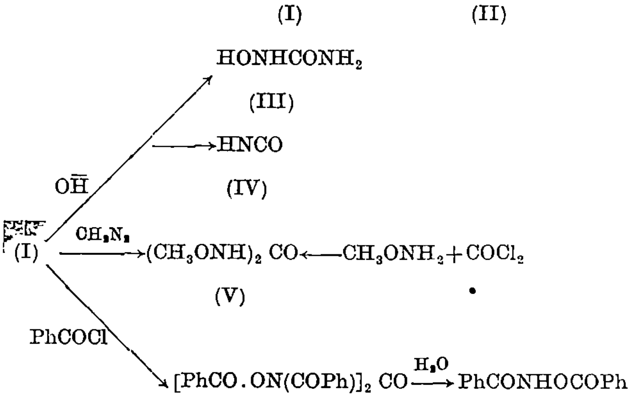
BIOCHEMISTRY

Dihydroxyurea

SEVERAL derivatives of hydroxylamine[1], including hydroxyurethane, *N*-methylhydroxylamine and hydroxyaminoacetic acid, cause chromosome abnormalities in mouse embryo and Chinese hamster cells similar to those induced by hydroxylamine[2]. Similar chromosomal abnormalities are also induced in anaphase and metaphase chromosomes of the root tips of *Vicia faba* by hydroxylamine, methyl-, ethyl-, *n*-propyl-, and *n*-butyl-*N*-hydroxycarbamates (S. H. Revell and K. S. Peggie, personal communication). Urethane appears to produce many radiomimetic effects through the metabolite *N*-hydroxyurethane to which it is converted by animals[3]. Although urea and urethane are inactive in these systems, hydroxyurea[1] and *N*-hydroxyurethane[3] are active; hydroxyurea is also an anti-tumour agent which is active against the *L*1210 leukæmia in mice[4]. It has been proposed[1,3,5,6] that these hydroxylamino derivatives may exercise their effects by a common chemical mechanism involving the production of nitroxyl or hydroxylamine *in vivo*.

In view of the effects on chromosomes and anti-tumour properties of hydroxyurea, dihydroxyurea has been prepared with the view of its possible use as a cancer chemotherapeutic agent. So far as we are aware, this compound has not been described in the literature. Hydroxylaminolysis of hydroxyurethane in ethanolic potassium hydroxide yielded hydroxyurea as the main product, which was also obtained from the reaction of phosgene (in toluene) with hydroxylamine in aqueous sodium carbonate. When phosgene (in dioxan) was allowed to react with an aqueous-dioxan suspension of hydroxylamine and potassium acetate at 0°, two main products were obtained: (I) colourless prisms which decomposed with partial melting at 102°–106° and (II) colourless plates which exploded at 95° or at room temperature after several hours. Both compounds reduced ammoniacal silver nitrate, gave red and unstable mauve to purple complexes with sodium pentacyanoammine ferroate and ferric chloride, respectively, and red condensation products with *p*-dimethylaminocinnamaldehyde. Compound (II) was probably the metastable hydroximic acid form (II) of dihydroxyurea (I).

$$\underset{}{COCl_2 + NH_2OH} \rightarrow \underset{(I)}{CO(NHOH)_2} + \underset{(II)}{HONH.C(OH) = NOH}$$



The structure (I) of the compound is indicated by the following: (*a*) The compound had the correct elemental (C, H and N) analysis. (*b*) The infra-red spectrum showed a strong carbonyl absorption near 6μ, and in the 3μ region a very broad, intense and featureless absorption centred around 3,200 cm⁻¹. The 3μ absorption appears to be typical of compounds containing the $-NHOH$ group: the spectrum of the solid $CH_3OCONHOH$ showed a similar absorption centred at 3,270 cm⁻¹, while liquids of the general type $R\mathrm{OCONHOH}$, where $R = \mathrm{C_2H_5}$, $\mathrm{CH_3(CH_2)_2}$, and $\mathrm{CH_3(CH_2)_3}$, gave similar bands centred near 3,300 cm^{-1}. Hydroxyurea showed a similar absorption, but with the bands due to the asymmetric and symmetric modes of the $\mathrm{NH_2}$ group superimposed at 3,422 cm^{-1} and 3,315 cm^{-1}, respectively. (*c*) The compound was unstable in alkaline media yielding hydroxyurea (III) and cyanic acid (IV) (detected and estimated via its blue Co^{2+} complex) as two of the decomposition products. (*d*) On treatment with diazomethane in methanol–ether, the compound yielded *N,N′*-dimethoxyurea (V) as a major reaction product which was identical with the authentic substance synthesized by reaction of phosgene with *O*-methylhydroxylamine. (*e*) With benzoyl chloride in pyridine at 0°, it yielded *N,N′,O,O′*-tetrabenzoyldihydroxyurea (VI), which, in boiling aqueous ethanol, yielded *O*-benzoyl benzohydroxamic acid (VII).

Preliminary experiments indicate that dihydroxyurea is more than five times as active as hydroxyurea in the induction of chromosomal aberrations in the root tips of *Vicia faba* (S. H. Revell, personal communication).

We thank Dr. S. H. Revell and Miss K. S. Peggie for the experiments with *Vicia faba*, and Dr. R. Lumley Jones for the infra-red determinations. This work was supported by grants to this Institute from the Medical Research Council and the British Empire Cancer Campaign for Research, and by the Public Health Service Research grant *CA*-03188-08 from the National Cancer Institute, U.S. Public Health Service.

Concentrating Protein Solutions

The earliest method of concentrating solutions of labile proteins, drying from the frozen state *in vacuo*, has several disadvantages, some of a technical and others of a fundamental nature such as increase in salt concentration and the proneness of complexes of proteins with lipids and some other substances to denaturation on freezing and drying. The alternatives are removal of water by dialysis of the protein solution against concentrated solutions of dextran or polyethylene glycol[1] of molecular weights sufficiently high not to penetrate the walls of the 'Cellophane' dialysis sac, or absorption of the water by shaking the protein solution with dispersed, cross-linked dextran ('Sephadex')[2]. These methods avoid freezing and drying and allow the salt concentration to be maintained at any desired value. However, dialysis is time-consuming to set up if many small samples are involved, and considerable losses can occur on the walls of the sac when the removal of 0·1–0·5 ml. of viscous protein solution is attempted. Removal of the water with 'Sephadex' is simple to carry out, but there is sometimes considerable loss of trace proteins by adsorption on to the large surface presented by the gel particles. This led me to consider the possibility of using rods of dried hydrophilic gel to remove the water from protein solutions while maintaining constant ionic strength.

The rods used in the experiments were prepared by polymerizing an aqueous solution containing acrylamide (15·2 g/100 ml.) and *N,N*-methylenebisacrylamide (0·8 g/100 ml.) in silicone-coated 0·5 cm × 20 cm glass tubes. In the course of diffusion experiments it has been established that substances with molecular weights greater than 10,000 do not significantly penetrate acrylamide gels of this degree of cross-linking and concentration (Curtain, unpublished results). Polymerization was initiated by adding 0·4 g of ammonium persulphate and 0·2 ml. of dimethyl amino-propionitrile to each 100 ml. of monomer solution. For convenience in handling the activated mixture, polymerization could be retarded for 15 min by adding 100 mg of potassium ferricyanide to each 100 ml. of solution. The silicone-coated glass tubes were prepared by dipping air-dried, acid-washed glass tubes in undiluted General Electric 'Drifilm' chlorosilane for 30 sec. The tubes were then washed for 10 min in running distilled water and dried in an oven at 150° C for 2 h. The life of the coating appears to be indefinite.

The rods of polymerized gel were removed from the tubes by pushing with a close-fitting glass rod and washed with six twelve-hourly changes of excess distilled water. They were then cut into convenient lengths (3–6 cm) and exposed in an open dish to the draught from the cooling unit of a 4° C cold room. After 96 h the rods had dried to 20 per cent of their original diameter and 90 per cent of their original length. It was found that more rapid drying at higher temperatures produced cracks in the rods. The rods may be kept indefinitely in a desiccator over phosphorus pentoxide. On equilibration with water for 18 h the rods attained their original volume, indicating a water regain of approximately 5·2 g/g.

For drying, protein solutions were placed in a test-tube of a diameter 3–4 mm greater than that of the swollen diameter of the rod (0·75 cm). A length of dry rod was then dropped into the protein solution. The amount of rod required to effect a given reduction in volume may be calculated readily from the water regain of the gel. In practice it was found that a ten-fold concentration could be obtained easily with volumes as low as 1 ml. For smaller volumes thinner rods (0·4 cm) were tried and in this case it was found practicable to concentrate volumes of 0·4 ml. down to 0·04 ml.

Possible loss of protein or denaturation was measured in two ways. 2 ml. of serum was concentrated to 0·2 ml. and then diluted to 2 ml. with 0·9 per cent (w/v) sodium chloride solution. Samples of the original serum and samples of the concentrated and diluted serum were examined by moving boundary electrophoresis and by micro-immunoelectrophoresis. The moving boundary electrophoresis was carried out in a Tiselius apparatus fitted with the phase-plate gradient interferometric optical system of Moore and Opperman[3] using pH 8·6, $I = 0{\cdot}1$ sodium veronal buffer. Duplicate runs of each sample were carried out and the ordinates of the gradient curves obtained by measurement of the interference fringes[4] directly compared for each run. Recovery of all components averaged 100 per cent within the limits of precision of the techniques used (0·7 per cent). The micro-immunoelectrophoretic patterns of the two samples were enantiographic, suggesting that no alteration had occurred in any of the components resolved by this technique.

I thank Dr. A. Baumgarten for carrying out the immunoelectrophoresis run.

Purine- and Pyrimidine-specific Antibodies: Precipitation with Denatured Deoxyribonucleic Acid

ANTIBODIES capable of reacting with thermally denatured DNA can be elicited by immunization with antigens prepared by coupling purine and pyrimidine derivatives to proteins[1–3]. In this way antibodies specific for the purinoyl moiety[1], for 5-acetyluracil[2] and for the five major bases[3] of DNA and RNA have recently been produced. Their reaction with thermally denatured DNA was demonstrated by means of a quantitative complement-fixation test, but initial attempts to obtain precipitation reactions with them were unsuccessful. We now offer evidence that precipitation reactions can occur between purine- and pyrimidine-specific antibodies and denatured DNA.

The methods of obtaining the antisera have been described[1–3]. Calf thymus DNA was obtained from Nutritional Biochemicals, Inc. A solution containing 1 mg/ml. in 0·015 M sodium chloride, 0·0015 M sodium citrate was denatured by heating at 100° C for 10 min in the presence of 1 per cent formaldehyde, followed by rapid chilling in an ice bath. Chick embryo DNA was prepared from 10-day-old embryos by a modification of Marmur's procedure[4]. Quantitative precipitin analyses were performed as described by Kabat and Mayer[5] using the Folin–Ciocalteu method[6] for analysis of specific precipitates. Rabbit γ-globulin purified by chromatography on DEAE-cellulose and assayed by Kjeldahl analysis was used as a standard. DNA in the precipitate was determined by ultra-violet spectrophotometry after extraction with 10 per cent perchloric acid at 70° for 20 min, a procedure used by Deicher *et al.*[7] to extract DNA from precipitates formed with the sera of some patients with lupus erythematosus.

The reactions between calf thymus DNA, denatured in the presence of formaldehyde, and antisera with four different specificities (anti-adenosine, anti-ribosylthymine, anti-purinoyl, anti-5-acetyluracil) are illustrated in Fig. 1. Native DNA and DNA denatured by heat in the absence of formaldehyde did not precipitate with any of the antisera. Sera obtained from the rabbits before they were immunized did not react with DNA denatured in the presence of formaldehyde. Unlike the antisera shown in Fig. 1, antibodies specific for cytidine, guanosine and uridine failed to give a precipitate with this DNA preparation.

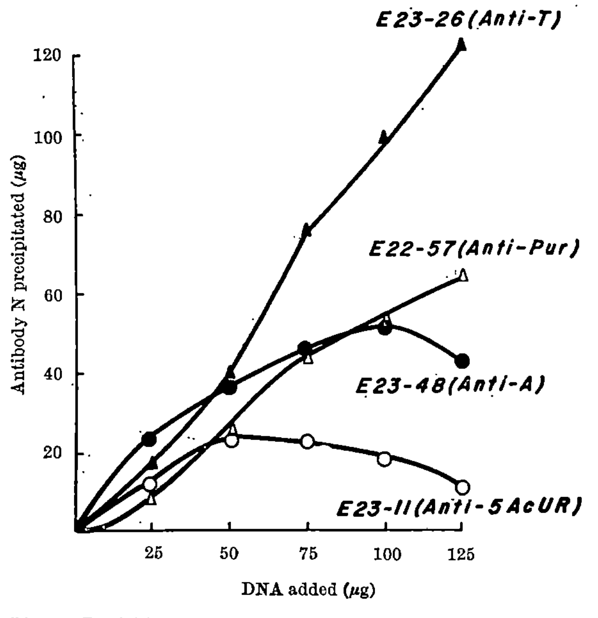

Fig. 1. Precipitin reaction between rabbit antisera (0·25 ml.) and calf thymus DNA thermally denatured in the presence of 1 per cent formaldehyde

The failure of anti-cytidine, anti-guanosine, and anti-uridine sera to yield a precipitate with formaldehyde-denatured DNA does not result from a low titre of specific antibodies, because precipitation with their homologous conjugated proteins showed that anti-cytidine, anti-guanosine, and anti-uridine sera contained, respectively, 329 µg, 270 µg and 254 µg of antibody N/ml. The anti-adenosine serum (E–23–48), which precipitated with formalinized calf thymus DNA (Fig. 1), contained only 149 µg antibody N/ml. Since the rabbits produced almost no antibody that was precipitable by the unconjugated serum albumins, these values are comparable with respect to concentration of specific antibody.

It is interesting in the case of the anti-adenosine and anti-ribosylthymine sera that essentially all the antibody which was precipitable by the conjugated protein also precipitated with DNA. On the other hand, only 22 per cent of the anti-5-acetyluracil antibody that reacted with the homologous conjugate was precipitable by DNA. Although the total antibody content of the anti-purinoyl serum has not yet been determined, it seems plausible to attribute the differences between the anti-5-acetyluracil, anti-ribosylthymine and anti-adenosine sera to the fact that the latter two are specific for bases present in the DNA molecule.

Only about 30 per cent of the formalinized DNA added to the antisera could be recovered from the specific precipitates, even in the zone of antibody excess. It would be of interest to determine whether the overall base composition of the DNA precipitated by each of the antibodies is the same as or different from that of the original DNA added; the latter finding would suggest that the antisera had effected a fractionation of the DNA. Our results are in contrast to those obtained by Deicher *et al.*[7], who, using the same procedure, found that all the DNA added to an excess of serum from a patient with lupus erythematosus could be extracted from the precipitate. Similarly, Murukami *et al.*[8], using antibody to phage *T* 4 DNA, found all the added DNA in the precipitates formed in the region of antibody excess. Although the antigen responsible for the antibody in the sera of lupus erythematosus patients is not known, it may be postulated to be DNA. Our results are explicable, then, if the reaction of DNA with lupus erythematosus serum and with anti-phage DNA serum is considered to be a reaction of an antigen with its homologous antibody, while, on the other hand, the reaction of the sera examined here is a cross-reaction, not necessarily leading to complete precipitation. Other factors, such as possible degradative effects of formaldehyde and heat on DNA, should also be considered. It may be noted, however, that Murukami *et al.*[8] used thermally denatured DNA in the investigations previously cited, and that Stollar and Grossman[9] have reported that formaldehyde increased the serological activity of thermally denatured *T* 4 DNA as measured by complement-fixation, presumably by preventing renaturation and/or intramolecular hydrogen bonding.

The observation that anti-guanosine and anti-cytidine antisera do not precipitate with formaldehyde-denatured calf thymus DNA may be ascribed either to the relatively low guanine-cytosine content (about 42 per cent) of calf thymus DNA[10] or to the fact that formaldehyde reacts most rapidly with the cytidylic and guanylic residues of DNA[11]. It may also be that the formaldehyde has caused a chemical change in the DNA which then enables it to precipitate with the other antisera. It would appear, however, that a reaction with formaldehyde is not required for precipitation since chick embryo DNA, which has been thermally denatured in the absence of formaldehyde, precipitates with the same antisera that react with formaldehyde-denatured calf thymus DNA. The failure of calf thymus DNA denatured in the absence of formaldehyde to precipitate with antisera may be due to some renaturation. Thermal transition curves[12] of such DNA show a hyperchromicity of 19·5 per cent, whereas none is seen with DNA denatured in the presence of formaldehyde. Thermally denatured chick embryo DNA, on re-heating, resembles formaldehyde-denatured calf thymus DNA and shows only a slight hyperchromic effect. These observations, together with the fact that chick embryo DNA also has a relatively low guanine-cytosine content (41 per cent)[10], support the suggestion made above, that the composition of DNA influences its reaction with antibody. Therefore, DNA's of varying base composition are being prepared in order to examine their precipitability with the antisera. If a correlation between the base specificity of an antibody and its reaction with DNA molecules of varying G–C content were found, such studies could provide a basis for using immunochemical methods in more subtle investigations of the structure of DNA.

A $C_{15}H_{22}O_4$ Compound produced by the Fungus *Aspergillus fischeri* var. *glaber*

IN late August 1962, Dr. C. W. Hesseltine of our laboratory collected a dry soil sample from under a Douglas fir in House Rock Camp Grounds near Corvallis, Oregon. From this sample was isolated a strain of *Aspergillus fischeri* var. *glaber* Fennell and Raper, now maintained in the A.R.S. Culture Collection as *NRRL* 3088.

During our culture work with this strain, we observed abundant crystal formation after about 6 days when the fungus was grown on malt extract agar. In still culture, as much as 4·87 g of crystalline product per litre of culture liquor was produced in 45 days at 28° C. The medium had the following composition: malt extract, 20 g; peptone, 1 g; *d*-glucose, 20 g; and distilled water, 1,000 ml.

The new fermentation product was isolated by filtration of the culture liquor and by acetone extraction of the dried mixture of mycelium and crystals. The compound separated from the acetone–hexane as colourless needles which melted at 49°–50° C. On cooling, molten samples crystallized and then melted at 54°–55° C. The compound has $[\alpha]_D^{20} - 40°$. Elementary analyses and a Signer molecular weight determination were in agreement with a molecular formula of $C_{15}H_{22}O_4$. Preliminary chemical and spectroscopic investigations indicate that the substance is a dilactone.

When compared with the type strain of *A. fischeri* var. *glaber* (described by Fennell and Raper[1] and deposited in our collection as *NRRL* 2163), strain *NRRL* 3088 differed only in being somewhat darker in colony colour, in lacking a faint pinkish reverse in the medium, and in having slightly larger cleistothecia. One sub-culture of the type strain also produced a few scattered crystals in malt extract agar after repeated transfer. Several other isolates of the variety produced no crystals.

Note added in proof. Since submission of this manuscript it has come to our attention that Brookes, Tidd and Turner[2] recently reported that *Aspergillus avenaceus* produces a $C_{15}H_{22}O_4$ product apparently identical with our lactone, judging from its double melting point, rotation and nuclear magnetic resonance spectrum.

Pyridoxine Deficiency in the Rat produced by D-Penicillamine

D-PENICILLAMINE is used in the treatment of Wilson's disease[1] and in cases of lead poisoning[2]. Recently, Crawhall *et al.*[3] reported that the administration of D-penicillamine to two cystinuric patients resulted in a marked fall in the excretion of cystine in urine. This was believed to be due to disulphide exchange resulting in the formation of the mixed disulphide of D-penicillamine and cysteine. It has therefore been suggested that D-penicillamine might prove useful in the management of this condition.

In a series of investigations, Du Vigneaud and his collaborators[4–6] showed that the inclusion of L-penicillamine in the diet of white rats caused a depletion of vitamin B_6, resulting in inhibition of growth, reduced transaminase activity and abnormal excretion of xanthurenic acid following the administration of a test dose of tryptophan. They also showed that these effects could be prevented by inclusion of large amounts of pyridoxine in the diet. It was suggested that vitamin B_6 deficiency was the result of a chemical combination between L-penicillamine and pyridoxal phosphate to form a thiazolidine structure.

Similar results on transaminases were observed by Heddle *et al.*[7], who, however, investigated the effect of DL-penicillamine on white rats.

Ueda *et al.*[8] demonstrated that, like the L-isomer, D-penicillamine reacts non-enzymatically with pyridoxal phosphate to form a thiazolidine compound. It was therefore considered of interest to examine whether B_6 deficiency resulted in the rat following the administration of D-penicillamine.

Six male albino rats (300–340 g wt.) were maintained on Oxoid rat diet (Oxoid, Ltd.). Before starting the administration of D-penicillamine the rats were placed in metabolic cages and 24 h urine was collected before and after subcutaneous injections of a test dose (40 mg/rat) of L-tryptophan[9]. A solution of 50 mg D-penicillamine hydrochloride (Dista Products, Ltd.) was given, by stomach tube, twice daily to each of three rats (Group *A*). The other three rats received the same dose by intramuscular injection (Group *B*). Since solutions of penicillamine were strongly acidic, adequate amounts of sodium bicarbonate were always added to bring the *p*H to neutrality. After a period of four weeks 24 h urine was collected again before and after injections of 40 mg L-tryptophan.

Aliquots of all urine collections containing 3·5 mg of creatinine were chilled in ice, acidified (*p*H 2) and extracted three times with equal volumes of ethyl acetate. The combined ethyl acetate extracts were evaporated to dryness under reduced pressure and the residue in each case was dissolved in 1 ml. of absolute ethanol. Fifty µl. of each sample was then chromatographed on Whatman No. 1 paper using butanol/acetic acid/water (4 : 1 : 5) as the solvent[10]. The dried papers were sprayed with diazotized sulphanilic acid and the results are shown in Fig. 1.

The intense spots (R_F 0·58) level with the xanthurenic acid marker consisted predominantly of xanthurenic acid, but smaller amounts of kynurenic acid were also present. This was established by two-dimensional chromatography of the ethyl acetate extracts using 20 per cent potassium chloride as the second solvent[11], when the mixture in each case was resolved into two substances both having a characteristic blue fluorescence. Their R_F values were 0·25 and 0·42 respectively[11], and both reacted with Pauly's reagent to produce a red colour.

In order to estimate xanthurenic acid the appropriate spots, located on another chromatogram in ultra-violet light, were cut out and eluted with 5 ml. of *tris*-buffer (*p*H 7·8). An aliquot was then used for the colour reaction with ferric ammonium sulphate as described by Wachstein and Gudaitis[12]. Values are shown in Table 1.

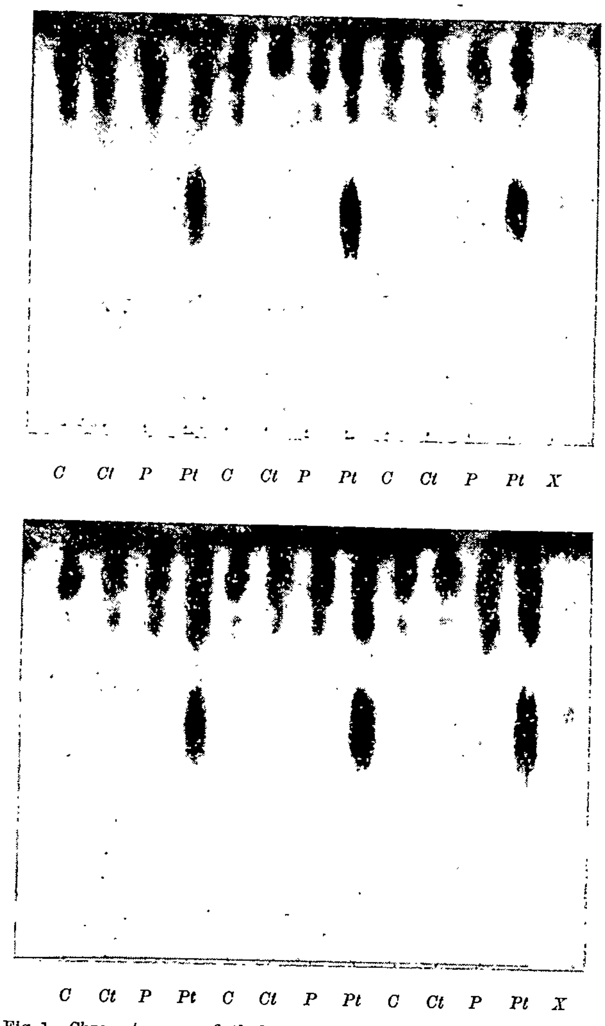

Fig. 1. Chromatograms of ethyl acetate extracts of urine run in butanol/acetic acid/water and sprayed with diazotized sulphanilic acid. Above, 3 rats oral D-penicillamine; below, 3 rats parenteral D-penicillamine. *C*, control urine before tryptophan; *Ct*, control urine after tryptophan; *P*, urine after D-penicillamine without tryptophan load; *Pt*, urine after D-penicillamine with tryptophan load; *X*, xanthurenic acid marker. Only urine *Pt* in each case shows a gross rise in xanthurenic and kynurenic acids

Table 2

R_F		Fluorescence in ultra-violet light	Ehrlich's reagent	Ekman's reagent	Pauly's reagent
Butanol: acetic acid: water (4 : 1 : 5)	20% KCl				
(*a*) 0·75	0·73	Green	Orange	Brown	Red (fades)
(*b*) 0·80	0·82	Blue	Orange	Magenta	—

Two other metabolites excreted in increased amounts, judging from their intense fluorescence in ultra-violet light, were further investigated by two-dimensional chromatography[11] followed by use of spray reagents as described by Dalgliesh[13]. The characteristics of the two metabolites are noted in Table 2.

These observations suggest the probable identity of the metabolites as (*a*) *N*α-acetyl-3-hydroxykynurenine; (*b*) *N*α-acetyl kynurenine, two intermediate metabolites of tryptophan[13].

From the results of experiments described here it is evident that following the ingestion of D-penicillamine over a period there is a considerable increase in excretion of certain intermediate metabolites of tryptophan after a test dose of the amino-acid. The abnormal excretion of xanthurenic and kynurenic acids as an indication of pyridoxine deficiency[9,13,14] has received further support from enzymatic work by Weber and Wiss[15], who studied the influence of vitamin B_6 depletion on various enzymes involved in the metabolism of tryptophan. They showed that in rat liver kynureninase is much more affected than kynurenine-2-oxo-glutarate-transaminase and concluded that the gross excretion of xanthurenic acid observed in pyridoxine deficiency could be attributed to the different behaviour of the two enzymes. It is therefore concluded that D-penicillamine, like the L-isomer, causes a depletion of pyridoxal-5-phosphate in the rat.

The results of these experiments on rats emphasize the prudence of including large amounts of pyridoxine in the diet of patients receiving D-penicillamine. Furthermore, as suggested by Evered[16], these patients need to be screened periodically for possible signs of vitamin B_6 deficiency.

I thank Prof. M. D. Milne for his advice.

Cytochemical Investigations of Deoxyribonucleic Acid-mediated Control of Ribonucleoprotein Metabolism

THE interdependence of various types of macromolecular synthesis in the cell has been demonstrated by the use of various antimetabolites. Synthesis of some ribonucleoproteins (RNP) in the nucleus is dependent on continued formation of deoxyribonucleic acid (DNA)[1–3]. One of these ribonucleoproteins is present in the nucleolus in the form of spherules called 'nucleolini'[3]. When synthesis of DNA was inhibited by 5-fluorodeoxyuridine (FUDR), the nucleolini were at first enlarged and later disappeared. The pars amorpha of the nucleolus was not reduced during this process[3]. Further cytochemical observations and biochemical investigations of HeLa cells, grown as previously described[3], and treated with 2×10^{-5} M FUDR are presented here.

Cells were stained by the toluidine blue–molybdate method[4]. Nuclear and cytoplasmic fractions were prepared by the citric acid procedure[5]. Nucleic acids were estimated by a modified Schmidt–Tannhauser procedure[6], Burton's modification of the Dische reaction[7] and the orcinol reaction[8]. Protein was determined by the method of Lowry *et al.*[9]. The results presented in Table 1 show that, during a period of 48 h, synthesis of DNA, nuclear RNA and protein was inhibited by FUDR. Examination of stained preparations made at intervals during the 48-h period indicated that the nucleolini and the chromosomal, perichromosomal and granular cytoplasmic RNP[4] gradually disappeared. The cytoplasmic changes occurred later than those in the nucleus. Cytochemical investigations have indicated that the nucleolini, chromosomal and so-called 'perichromosomal' RNP appear to exist as hybrids with DNA[10]. The changes were not due to conversion of FUDR to fluorouracil, since they could be prevented by incorporation of equimolar thymidine, but not by uridine in the medium[11].

Table 1. EFFECTS OF FLUORODEOXYURIDINE (FUDR) ON NUCLEIC ACIDS AND PROTEIN PER CULTURE DURING 48-H INCUBATION*

	DNA	RNA	Protein
Untreated	407	390	506
Treated with FUDR (2×10^5 M)	95	86	159
Difference ± *S.E.*	312 ± 61	304 ± 53	347 ± 12

* Mean of four experiments.

Table 2. EFFECTS OF ACTINOMYCIN ON NUCLEIC ACIDS AND PROTEIN PER CULTURE DURING 24-H INCUBATION

Cultures	Percentage of initial amount per culture		
	DNA	RNA	Protein
Untreated	197	224	208
Treated with actinomycin (0·01 μg/ml.)	190	104	153
Difference ± *S.E.*	7 ± 14	120 ± 27	55 ± 25

* Mean of four experiments.

The results of similar investigations of HeLa cells treated with actinomycin *D* (0·01 μg/ml.) for 24 h are presented in Table 2. Treatment with actinomycin produced a pronounced inhibition of synthesis of RNA, some reduction of protein formation and no significant effect on DNA metabolism. Cytochemical investigations indicated that, after 24 h, the nucleolini and pars amorpha of the nucleolus had almost completely disappeared and that the granular cytoplasmic RNP was decreased. Sequential observations revealed that the nucleolar changes preceded the decrease in cytoplasmic RNP. Chromosomal and perichromosomal RNP were unaffected.

In summary, the results with FUDR show that inhibition of synthesis of DNA results in a failure of synthesis of DNA–RNA hybrids in the chromatin and nucleolini; granular RNP in the cytoplasm is also reduced. Inactivation of DNA-primed RNA synthesis by actinomycin[12], on the other hand, inhibits the formation of RNA in all parts of the nucleolus, and later results in the reduction of granular RNP in the cytoplasm. The work of Perry indicates that low concentrations of actinomycin, such as those used here, may selectively inhibit the formation of rapidly labelling high molecular weight ribosomal-precursor RNA in the nucleolus, and later lead to a decrease in ribosomal RNP[13]. This would suggest that at least one of the ribonucleoproteins of the nucleolus is a precursor of the granular cytoplasmic RNP which is, therefore, probably of the ribosomal or polyribosomal type. Since the RNP of the nucleolini and not the pars amorpha was affected in the FUDR system, in which the granular cytoplasmic RNP was also reduced, the RNP of the nucleolini may be of the ribosomal precursor type. On the other hand, as previously suggested[3,6,14–16], it may be of the messenger type, since the latter is necessary for the formation of ergosomes or polyribosomes[17] and only large aggregates of ribosomes could possibly be visualized by cytochemical techniques for light microscopy.

Anomalous Ionization of Methyl Linolenate by Metastable Argon Atoms: Possible Linolenic Acid Participation in Photosynthetic Reactions

DURING the past few years there has been an increasing number of reports pointing to the possible specific role of α-linolenic (*cis*-9,12,15-octadecatrienoic) acid in photosynthetic reactions of green plants. In algal cells grown in the dark α-linolenic acid is virtually absent; if the cells are exposed to light, the concentration of linolenic acid increases in parallel with that of chlorophyll[1]. The same process has been observed during the greening of etiolated *Citrullus vulgaris* seedlings[2].

Approximately 85 per cent of the cellular α-linolenate is accounted for by the chloroplast fraction[3] as an acyl component of galactolipids of the chlorophyll–lipoprotein membranes[4]. According to Bloch *et al.*, the presence of linolenic acid in *Euglena gracilis Z* cells seems to be necessary for the Hill reaction and the evolution of oxygen[3].

The present-day concept of photosynthesis involves the absorption of light quanta by a chlorophyll molecule followed by the conversion of the latter to a triplet excited state. The excitation energy is transferred by a mechanism as yet obscure to a photochemical reaction centre to effect photolysis of water and simultaneous oxygen evolution[5]. It has been suggested that the linolenic acid of chloroplasts is in some way related to the dark reactions of electron transfer[3].

Having at present no means of devising a model system of photosynthesis containing linolenic acid, we decided to compare the capability of linolenic acid and other fatty acids commonly present in plant tissues to be ionized in a more simple model system by excited metastable atoms. It is known that in the ionization detector for gas chromatography introduced by J. E. Lovelock[6] the organic substances are ionized as a result of the following reactions:

$$\text{Ar} + \beta\text{-particles } (\text{Sr}^{90}) \rightarrow \text{Ar}^{+} + e^{-} \quad (1)$$

$$\text{Ar} + e^{-} \rightarrow \text{Ar}^{*} \quad (2)$$

$$\text{Organic substance} + \text{Ar}^{*} \rightarrow \text{organic substance}^{+} + \text{Ar} \quad (3)$$

where e^{-} are free electrons, Ar^{*} are metastable argon atoms and organic substance^{+} are ionized molecules of organic substance[7].

A standard mixture of palmitic, stearic, oleic, linoleic and α-linolenic acid methyl esters (0·25–0·50 µl.) was introduced into the ionization detector of an argon chromatograph (W. G. Pye and Co., Ltd., Cambridge, Great Britain) containing ^{90}Sr (20 mc.) at 190° ± 1°, 60 ml. Ar/min and × 10 or × 3 amplifier sensitivity. In various experiments the detector voltage was 750, 1,000, 1,250 or 1,500 V. Detector responses proportional to the ionization of different esters were determined by multiplication of the respective peak heights by width at mid-height, or by triangulation[8], and expressed in arbitrary units in relation to methyl palmitate: the mass response for methyl palmitate being equal to 1 in each experiment.

The effect of detector voltage on the ionization of fatty acid methyl esters is shown in Fig. 1. These results demonstrate that detector voltage has almost no effect on the relative response for palmitic, stearic, oleic and linoleic acid esters. Therefore, these acids do not vary in their ionization pattern. On the contrary, the ionization of methyl linolenate rises continuously when β-particle energy and metastable atom concentration are increased.

It is suggested that the unique properties of linolenic acid with regard to its ionization pattern and predominant role in photosynthetic reactions are related to the structure of this acid having three methylene-interrupted double bonds at the 'methyl end' of the aliphatic chain. This suggestion is all the more probable as there are other instances when the structure of unsaturated fatty acids controls their biological function. Linoleic (*cis*-9,12-octadecadienoic) and arachidonic (*cis*-5,8,11,14-docosatetraenoic) acids are essential to animal organism (vitamin F) (ref. 9). These acids can be replaced by the intermediate of their interconversion, γ-linolenic (*cis*-6,9,12-octadecatrienoic) acid[10], which is, however, completely inactive in photosynthetic systems[3].

Thus the anomalous ionization of methyl linolenate by excited metastable atoms does not explain the mechanism of α-linolenic acid participation in 'primary' photosynthetic reactions. Nevertheless, we may hope that the found relationship will be useful in planning and carrying out further experiments in this field.

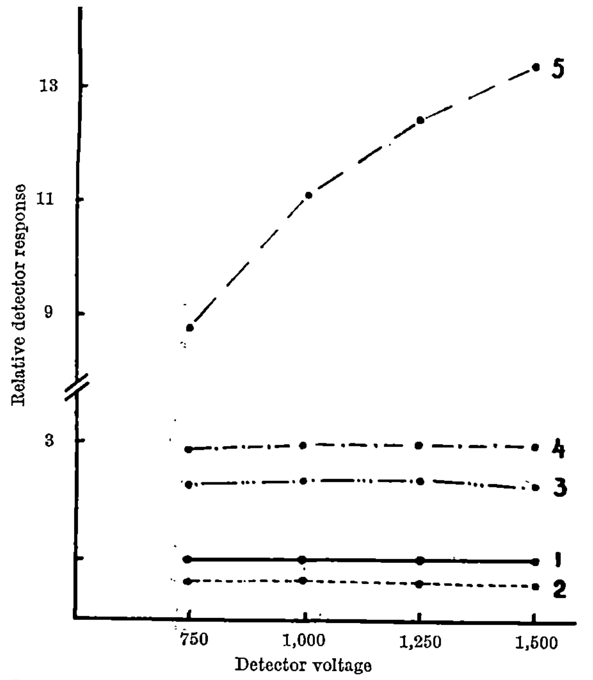

Fig. 1. Relative ionization detector response for fatty acid methyl esters as a function of detector voltage. The response for methyl palmitate is arbitrarily equal to 1 at each voltage. 1, methyl palmitate; 2, methyl stearate; 3, methyl oleate; 4, methyl linoleate; 5, methyl linolenate

PHYSIOLOGY

Inhibition of Ovulation in the Rabbit by Actinomycin *D*

In the rabbit, an induced ovulator, sufficient gonadotropin is released in the first hour after coitus to result in ovulation 9 h later[1]. This represents an interesting example of a stimulus-response system. Although the stimulus pathway has been reasonably elucidated, the response is not well understood. The subsequent steps in the response beyond the level of release of gonadotropin, involving interaction of hormone and ovary and culminating in rupture of the Graafian follicle, are unknown. For about 8 h after the coital stimulus the only apparent change in the follicle is an increased protuberance of the follicle above the surface of the ovary. It is during the 2 h prior to rupture of the follicle that a rapid increase in volume occurs. The increased volume is followed by stigma formation, usually at the apex of the follicle, and finally the release of the ovum.

Several hypotheses have been suggested to account for the changes which have been seen. These vary from the suggestion that smooth muscle in the theca externa facilitates rupture to the suggestion that an increase in pressure in the follicle is the causative mechanism via a depolymerization and an ischæmia of the stigma followed by necrosis[2]. More recently the concept of increased pressure was made untenable by the demonstration that existent pressures remain unchanged through ovulation[3]. A model of the mechanism of ovulation has been described in which it was shown that bacterial collagenase or protease injected into the antrum of unstimulated follicles could cause swelling, stigma formation and rupture[3]. The presence of proteinases with optima at *p*H 4 and 8 in the ovaries of cycling rats in concentrations above those seen in pseudopregnant and pregnant rat ovaries also fits into the picture in which enzymes play a part in ovulation[4].

Actinomycin *D* appears to inhibit the action of several hormones[5]. It is at present believed that actinomycin *D* is an extremely specific inhibitor of protein synthesis and that it acts by blocking DNA-directed synthesis of messenger RNA, perhaps by binding with the guanine in the minor groove of the DNA primer and thus preventing the action of RNA polymerase[6]. Therefore, in the context of contemporary ideas of how actinomycin *D* acts, we explored the effects on the ovulatory mechanism subsequent to injection directly into stimulated Graafian follicles. We have determined both the minimal amount of actinomycin *D* necessary to inhibit ovulation and the most effective period after a coital stimulus for the action of the minimally effective dose.

Virgin female rabbits, individually caged and about 6 months old, were stimulated by mating with a vigorous buck. The rabbits were anæsthetized 1 h after coitus with approximately 25 mg of sodium pentobarbital/kg body wt. Bilateral laparotomies were performed and the ovaries pulled out without embarrassment of the circulation so that the follicles might be injected and examined. The ovaries were supported with a 'Plexi-glass' rod and kept warm and moist with a drip of 37° C Ringer's solution[3]. The micropipettes were inserted into mature œstrus stage follicles with a DeFonbrune micromanipulator[3]. Randomly selected follicles were injected with either actinomycin *D* or saline so that each ovary contained, frequently in close proximity to each other, both treated and control follicles. The follicles were examined for ovulation 11 h after coitus and re-examined periodically for as long as 24 h to check for delayed ovulation in follicles that had failed to ovulate initially. The data for the entire ovary were discarded if all saline-injected follicles failed to ovulate. In no case did actinomycin-*D*-injected follicles ovulate when the saline-injected follicles failed to ovulate.

Eighty-five per cent of the 33 follicles injected with 1 µl. of isotonic saline ovulated. Fifty-seven follicles in 13 rabbits in œstrus that were stimulated by mating were then injected with 1 µl. of actinomycin *D* in saline to determine the minimum concentration necessary to inhibit ovulation. The follicles were all injected 1–3 h after coitus with one of the several doses of actinomycin *D* indicated in Fig. 1. Doses of 1 µg–10^{-3} µg actinomycin *D* completely inhibited ovulation while doses less than 10^{-3} µg actinomycin *D* caused only occasional inhibition (Fig. 1).

Post-coital inhibition time was determined by injections of actinomycin *D* into follicles at various times after the coital stimulus. A dose of 10^{-3} µg was used in these experiments. Thirty-seven follicles were injected in 9 stimulated œstrus rabbits. There was complete inhibition of ovulation when the follicles were injected 1–3 h after coitus; later injections resulted in only occasional or no inhibition (Fig. 2).

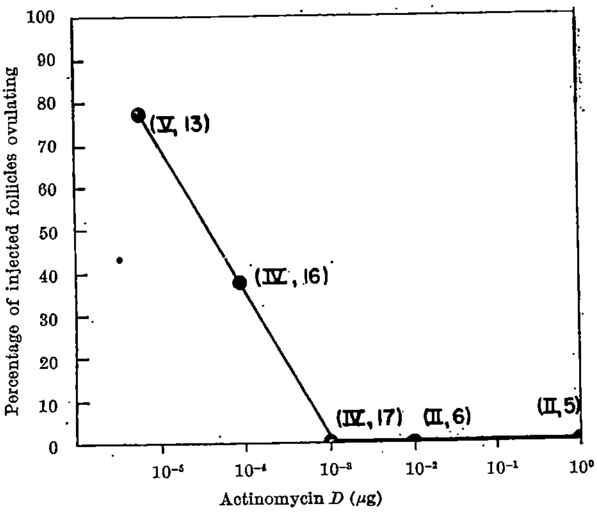

Fig. 1. Effect of actinomycin *D* on ovulation. The drug was injected directly into the œstrus stage follicle 1–3 h after a coital stimulus to the rabbit. Saline was always injected into several follicles in the same ovary and the response was ovulation of these follicles. 85 per cent of the saline-injected follicles ovulated. The response was recorded 11 h after the stimulus had been administered. Roman numerals, No. of animals; Arabic numerals, No. of follicles

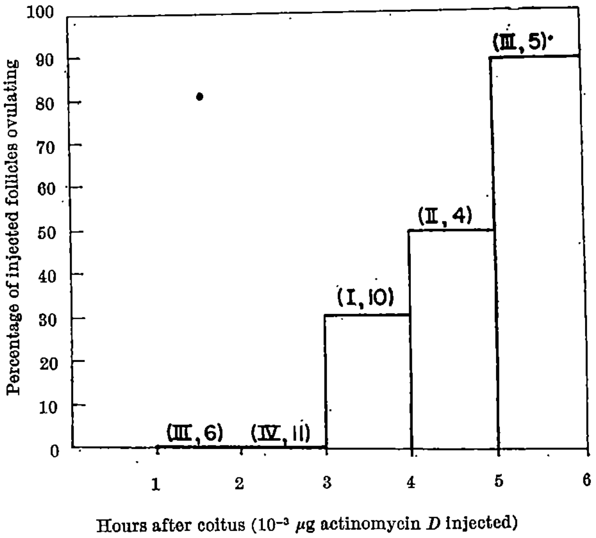

Fig. 2. Post-coital inhibition time. The rabbits were anæsthetized 1 h after coitus and the follicles injected with actinomycin *D* at the times indicated. The ovaries were examined after 11 h and after 24 h. Saline was injected into control follicles in each ovary. Evidence of inhibition of ovulation by actinomycin *D* was based on ovulation occurring in saline-injected follicles in the same ovary. Roman numerals, No. of animals; Arabic numerals, No. of follicles

Preliminary examination of the duration of inhibition of ovulation has been considered. Twenty-five I.U. of human chorionic gonadotropin was injected into 2 rabbits mated 26 h previously. The only non-ovulated Graafian follicles on the ovaries were those that had been injected with 10^{-3} µg actinomycin *D* 25 h earlier. Ten hours after the human chorionic gonadotropin had been administered the ovaries were again examined. Eleven inhibited follicles appeared greatly enlarged and hæmorrhagic and 2 follicles had ovulated. Therefore it appears that actinomycin *D* inhibition is transient and that such follicles are capable of response to a later second dose of ovulation inducing hormone.

Actinomycin *D* is an effective inhibitor of ovulation when injected into mature œstrus stage follicles in high enough concentrations and soon enough after the coital stimulus. Furthermore the inhibition is transient. In view of the effectiveness of actinomycin *D* as an inhibitor of ovulation and in keeping with present-day ideas of the mechanism of actinomycin *D* action we suggest that gonadotropin acts at the level of the nucleus of some as yet unspecified cells to induce the synthesis of a specific *m*-RNA. This *m*-RNA forms a template for the synthesis of a protein which may be intermediate in the synthesis of a hormone or may possibly be a proteolytic enzyme which then causes ovulation. It may be that sufficient messenger RNA is produced in the 3 h after coitus to allow adequate protein synthesis for ovulation to occur, since injection of 10^{-3} µg actinomycin *D* was completely inhibitory if given up to 3 h after coitus, but was only partially inhibitory or had no effect if injected later than 3 h.

This work was supported in part by a U.S. Public Health Service fellowship, 1 *FL GM*–21, 186–01 (W.R.P.), from the National Institute of General Medical Sciences, in part by a contract between the Division of Biology and Medicine, U.S. Atomic Energy Commission and the Florida State University, and in part by National Institute of Arthritis and Metabolic Diseases grant *AM*–01904.

The actinomycin *D* was provided by Dr. E. Alpert of Merck, Sharp and Dohme Research Laboratories.

Modification of Visual Critical Flicker Fusion Frequency by Intermittent Auditory Stimuli

KRAVKOV[1,2] found that visual critical flicker fusion frequency was modified by auditory stimuli, but other workers failed to confirm this[3,4].

The experiments to be described here were suggested by the demonstration of a modifying effect of intermittent light of varying frequency on critical flicker fusion frequency[5,6]. The relationship between critical flicker fusion frequency and the adapting frequency was almost linear between adapting frequencies of 24 and 54 c/s. Because the exposure of one eye to the adapting light altered the critical flicker fusion frequency of the other, the phenomenon is probably central in origin.

Visual critical flicker fusion frequency was measured by Turner's technique[6]. It was defined as the fastest rate at which the neon light source was considered to be flickering as opposed to being steady. The threshold was determined either by an approach from a lower to a higher frequency (ascending threshold) or vice versa (descending threshold). Audible 'clicks' of varying frequency were derived from an oscillator constructed on the 'module' system[7] and were presented to the subject through a loud speaker.

The ascending (*A*) and descending (*D*) thresholds of critical flicker fusion frequency of six subjects were tested after exposure for 1 min to auditory 'clicks' at 25 or at 50 c/s., or after a period of silence. The order in which the various frequencies of sound were given and ascending and descending thresholds were measured was randomized in a latin square arrangement. The results are given in Table 1.

Table 1. EXP. 1. EFFECT OF INTERMITTENT SOUND AT 25 AND 50 C/S ON ASCENDING (*A*) AND DESCENDING (*D*) THRESHOLDS OF CRITICAL FLICKER FUSION FREQUENCY (c.f.f.f.)

$n=6$ 5 per cent critical difference $=0\cdot74$ c/s

		Mean c.f.f.f. (c/s)	
		A	*D*
No sound		35·5	35·0
Adapting sound	25	36·0	35·0
frequency (c/s)	50	36·25	35·75

Table 2. EXP. 2. EFFECTS OF INTERMITTENT SOUND (0–80 C/S) ON ASCENDING (*A*) AND DESCENDING (*D*) THRESHOLDS OF c.f.f.f.

$n=8$ 5 per cent critical difference $=0\cdot54$ c/s

		Adapting sound frequency (c/s)			
		0	20	40	80
C.f.f.f.	*A*	35·25	35·5	37·0	36·75
(c/s)	*D*	35·25	35·75	35·75	36·5

The mean ascending threshold of critical flicker fusion frequency after exposure to sound at 50 c/s was significantly higher than that without sound, while that after 25 c/s had an intermediate value. The mean descending threshold after 50 c/s was significantly higher than that after 25 c/s or that without sound, these latter two having identical values.

In a second experiment using the same method but in a sound-proof room, adapting frequencies of 20, 40 and 80 c/s were used. Determinations were randomized to eliminate any order effect. Table 2 shows that visual critical flicker fusion frequency rose as the adapting auditory frequency increased. The ascending threshold rose sharply between 20 and 40 c/s while the descending threshold rose steeply between 40 and 80 c/s.

These preliminary experiments suggest that there is an intersensory effect of intermittent sound of varying frequency on critical flicker fusion frequency.

We thank Mr. P. M. G. Bell for the design of the apparatus.

PHARMACOLOGY

Effect of Snake Venom and Endotoxin on Cortical Electrical Activity

THE effects of a lethal injection of cobra venom, rattlesnake venom, or *E. coli* endotoxin on the cardiovascular system of the dog and monkey have been described previously in detail. The administration of endotoxin results in hypotension, acidosis, hæmolysis, and renal failure[1–4]. A similar effect is seen following the administration of snake venom[5,6]. No reports, however, describe the effects of these compounds on the central nervous system. The purpose of work recorded here, therefore, was to determine if a change in cortical electrical activity follows a lethal injection of these toxins.

Thirty adult mongrel dogs and fifteen monkeys of the Cynapthecoid group (sooty mangabey) were used. All animals were anæsthetized with pentobarbital sodium (30 mg/kg). Arterial blood pressure was continuously recorded using a Statham strain gauge and an *E* and *M* six-channel physiograph. The cortical electrical activity of the right and left hemispheres of the brain was monitored using bipolar silver electrodes placed directly on the dura of each hemisphere. Continuous electroencephalograms were recorded prior to and for up to 10 h after the intravenous administration of the toxin. The animals were divided at random into the following three groups:

Group I: 10 dogs and 5 monkeys receiving 0·5 mg/kg crude cobra venom (*Naja naja*); Group II: 10 dogs and 5 monkeys receiving 0·5 mg/kg crude rattlesnake venom (*Crotalus admanteus*); Group III: 10 dogs and 5 monkeys receiving 1·0 mg/g endotoxin (*E. coli*) (Difco).

Table 1 presents a composite of the results obtained from the three groups of animals used in this work. The effect of each toxin on cortical electrical activity is indicated. The change observed in EEG is of an all-or-none nature, being characterized by either a complete loss of activity, or no alteration at all. All animals in Groups I and II showed complete or almost complete EEG silence within 1 min after having received either venom. In contrast, none of the dogs or monkeys in Group III, which received endotoxin, showed any alteration in

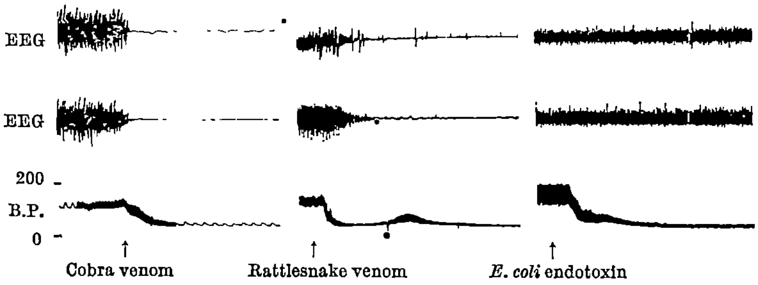

Fig. 1

EEG. Average survival time, as well as the range for each group, is indicated.

Actual tracings, representative of the changes observed in the three groups, are shown in Fig. 1. The immediate effect of cobra venom, rattlesnake venom, and *E. coli* endotoxin on EEG and blood pressure is presented. Within 30–60 sec following the administration of cobra or rattlesnake venom, a complete loss of all EEG activity is seen. This occurs prior to the initial fall in blood pressure. Although the hypotension is usually followed by partial recovery, no return of cortical activity is noted during the subsequent course of the experiment. All animals eventually expire exhibiting signs of respiratory paralysis and cardiovascular failure. In conjunction with the initial change in EEG, a loss of eyelid and corneal reflexes occurs shortly after venom, which, like the change in EEG, is irreversible. In the animals receiving endotoxin, a fall in blood pressure similar to that observed with snake venom is noted; however, no change in cortical electrical activity is observed. As both the dogs and monkeys progress into the later stages of endotoxin shock and the blood pressure once again falls to hypotensive levels, some changes in cortical activity are noted. These alterations are probably associated with and attributable to progressive anoxia and not to any direct action of endotoxin on cortical tissue *per se*.

Table 1

	Dogs			Monkeys		
	No. of animals	EEG change	Average survival time (h)	No. of animals	EEG change	Average survival time (h)
Group I (cobra venom)	10	10/10	1·4 (0·3–2·2)	5	5/5	2·0 (1·1–3·1)
Group II (rattlesnake venom)	10	10/10	1·1 (0·2–2·0)	5	5/5	1·7 (1·0–2·8)
Group III (*E. coli* endotoxin)	10	0/10	7·6 (5·1–9·6)	5	0/5	5·6 (4·1–10·0)

Results of this work indicate that the venoms of the hooded cobra and of the eastern diamondback rattlesnake have a unique and severely depressant effect on cortical electrical activity. No comparable change is observed after the administration of endotoxin, even though the resulting fall in blood pressure is in many instances greater than that produced by snake venom. This observation, in conjunction with data obtained from hæmorrhagic shock investigations, in which prolonged hypotension does not produce changes in EEG[7], eliminates the probability that the observed change in EEG is the result of either cardiovascular hypotension and/or cerebral hypoxia. In addition, changes in cortical activity consistently appear before the observed fall in blood pressure, indicating that the toxin exerts a more immediate and profound effect on brain tissue than on peripheral components. The relationship of this change to that occurring at the neuromuscular junction of the diaphragm is not clear[8,9]. It is possible that the two are in some way related. The permanent loss of eyelid and corneal reflexes in conjunction with the change in EEG supports the hypothesis that both venoms are capable of severely disrupting not only the normal spontaneous electrical activity but also the functional organization of the brain. An investigation of the mechanisms by which this change is produced, as well as a fractionation of the venoms into their various components, is now being carried out in these laboratories.

The cortical electrical activity of the brain has been shown to be severely depressed by the administration of cobra and rattlesnake venoms. This change is not seen in animals administered a lethal dose of endotoxin, even though a fall in blood pressure similar to that observed with venom is consistently noted. The relationship of the EEG change to the lethal outcome of exotoxin shock is not clear but may in some way be related to its blocking effect on neuromuscular transmission.

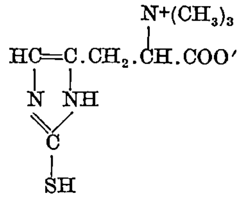
Identity of the Cerebellar Factor

EXTRACTS of mammalian cerebellum, suitably injected into the cerebral circulation of the decerebrate rabbit, produce an increase in the electrical activity of the cerebellum. This effect, first described by Crossland and Mitchell[1], is due to a hitherto unidentified substance, provisionally called the cerebellar factor. The cerebellar factor has been found in some other localized regions of the nervous system, particularly the optic nerves. It is present in small amounts in the cerebral hemispheres, but absent from the dorsal columns of the spinal cord[2]. A characteristic feature of the cerebellar factor is its greater stability in alkaline than in acid solutions. In alkali (pH 14) biological activity is still present after 5 min boiling, but it gradually disappears thereafter; in acid (pH 1) no detectable activity remains after boiling for 5 sec[2]. Although active on central neurones, the cerebellar factor appears to be inactive on smooth or striated muscle and on autonomic ganglia.

A study of the known chemical properties of the cerebellar factor suggested a similarity with ergothioneine, the betaine of thiolhistidine:



Ergothioneine shows the same relative stability towards acid and alkali as does the cerebellar factor. In acid solution its sulphydryl group is very easily oxidized but is quite resistant to oxidation in an alkaline medium. Under alkaline conditions, fission eventually occurs elsewhere in the molecule with the formation of thiolurocanic acid and the release of trimethylamine[3].

Ergothioneine is known to occur in some mammalian tissues, although earlier workers have reported its absence from brain[3], and Melville *et al.* have developed a highly specific and relatively sensitive method for its quantitative determination in tissue extracts[4]. We have applied the method to brain with the results, for the rabbit, given in Table 1.

Table 1. ERGOTHIONEINE CONTENT (IN μg/g) OF PARTS OF THE RABBIT CENTRAL NERVOUS SYSTEM

		Mean
Cerebellum	4·3, 4·6, 5·0, 5·5	4·9
Cerebral hemispheres	0·9, 1·2, 1·2, 1·3, 1·5	1·2
Optic nerves	21·0, 36·0, 29·0	28·7
Dorsal columns	< 1·0, < 1·0	< 1·0

A similar distribution has been found in other mammalian species: it corresponds to that found for the cerebellar factor. We have also found that ergothioneine has an action on the electrical activity of the cerebellum similar to that produced by the cerebellar factor. In sensitive preparations, 0·1 µg is sufficient to cause a marked increase in cerebellar activity. In their original experiments, Crossland and Mitchell were able to produce cerebellar excitation by the injection of an extract of 20 mg of rabbit cerebellum and this amount of tissue would have contained approximately 0·1 µg of ergothioneine (Table 1). Thus, the excitatory action of cerebellar extracts can be completely accounted for by their contained ergothioneine.

The actions of ergothioneine are probably not confined to the cerebellum. Preliminary experiments, in which ergothioneine has been applied to small groups of cells in the parietal cortex, using the technique developed by Mitchell[5], have indicated that it also excites some cortical cells. Outside the central nervous system it appears to be without detectable action.

Guanethidine as an Anti-fibrillatory Agent

CATECHOLAMINES have for many years been known to produce cardiac arrhythmias[1]. The influence of acetylcholine or vagal stimulation on arrhythmias, especially of the atria, has overshadowed the influence of the sympathetic mediators[2]. Sharma[3] has reported that administration of epinephrine or norepinephrine simultaneously with acetylcholine enhanced the fibrillatory activity of the latter. Thus, it would seem appropriate to examine further the relationship between acetylcholine and catecholamines in their effect on heart rhythm.

The introduction of guanethidine, a drug which acts at adrenergic nerve terminals by preventing release of norepinephrine on nerve stimulation, suggested the possibility of studying the susceptibility to experimental atrial fibrillation in animals with deficient adrenergic mechanisms.

Healthy male dogs weighing about 10 kg were premedicated with morphine sulphate (2 mg/kg subcutaneously). In 30 min, the dogs were anæsthetized with sodium pentobarbital (35 mg/kg intraperitoneally). An endotracheal tube was inserted and the dogs immobilized in the prone position. They were given guanethidine at various doses and intervals before and during the experiment (Table 1). The method of Leveque was used for the production of atrial fibrillation[4]. With this procedure during control tests, all the experimental dogs demonstrated susceptibility to acetylcholine-induced atrial fibrillation at doses of 0·3 mg/kg or less. A total of 26 experiments were performed on 14 dogs.

Table 1. DOSE AND DURATION OF ACTION OF GUANETHIDINE AS AN ANTI-FIBRILLATORY AGENT

117	2·5	,,	24	0	(2)
131	2·5	,,	24	0	(2)

The usual protective dose of guanethidine within 20 min appeared to be about 1·0 mg/kg although 0·5 was sometimes adequate. These low doses were protective for at least 1–2 h, but the effect did not usually last as long as 4 h. With increasing doses of guanethidine (up to 10·0 mg/kg), the anti-arrhythmic effect of this drug was prolonged up to 24 h.

Anti-fibrillatory drugs are in general related in structure to local anæsthetics and antihistaminic agents. The chemical structure of guanethidine shows similarities to this general structure, and Green has reported that guanethidine possesses a highly persistent local anæsthetic action[5].

Using the method described here for testing the anti-fibrillatory action of guanethidine, other drugs such as procaine, diphenhydramine, chlorpheniramine, tripelennamine and quinidine have been found previously to be protective[4].

It is interesting to note that the anti-arrhythmic action of guanethidine is apparent with doses that are smaller than those generally used for adrenergic blockade[6]. This might suggest that the anti-arrhythmic effect of this drug does not depend on changes in catecholamine stores. Investigations to elucidate the mechanism of action of guanethidine in preventing cardiac arrhythmias are now in progress.

IMMUNOLOGY

Suppression of Antibody to Endotoxin with 6-Mercaptopurine : Effect of Antigen Dose

THE selection of antigen, the type and dose of antimetabolite administered, and the species of recipient animal are all important factors in the evaluation of the immunosuppressive properties of antimetabolites[1]. Using as an antigen sheep red blood cells treated with tannic acid, Nathan *et al.* reported that suppression of antibody response by 6-mercaptopurine (6-MP) became greater as the dose of antigen was increased[2]. Furthermore, in investigations of drug-induced immunological tolerance, Schwartz and Dameshek have shown that using a constant dose of 6-MP, suppression of antibody to bovine serum albumin is proportional to dose of antigen administered[3]. We have used 6-MP to suppress the antibody response to the somatic antigens (endotoxins) of Gram-negative bacteria[4]. In contrast to the foregoing reports we have noted that suppression of antibody to bacterial polysaccharide antigens is not greater when larger doses of antigen are administered.

The endotoxin of *Salmonella typhosa* 0901 (Difco), diluted in sterile buffered saline, was administered intravenously to New Zealand albino rabbits of either sex weighing approximately 2 kg. Doses of 2, 20 or 200 μg in 2-ml. volumes were injected into three groups of experimental animals ; quantities greater than 200 μg were found to have prohibitive toxicity. 6-Mercaptopurine was prepared for injection immediately prior to use by dissolving a maximum of 150 mg of 6-MP for each ml. of 1 N sodium hydroxide. The solution was then diluted with buffered saline to a concentration of 18 mg/ml. and *p*H 10–11. All animals treated with 6-MP received 18 mg of drug/kg body wt. Control animals, not receiving 6-MP, were injected with identical volumes of a buffered saline solution adjusted to *p*H 10–11 by addition of 1 N sodium hydroxide. Both injections and bleedings were via marginal ear veins with all bloods obtained at least 24 h after the final injection of 6-MP and 5 days after the endotoxin injection, since peak antibody titres to endotoxins have been reported to occur at this time[5]. Sera, separated by centrifugation, were stored at −20° C until antibody determinations were made by the bentonite flocculation technique using serial two-fold dilutions of sera[6]. Numerous determinations of antibody to *S. typhosa* in normal rabbit sera previously made with this technique have revealed only rare positives with low titre ; therefore, antibody levels prior to endotoxin injection are not reported.

Animals were divided into three experimental groups : the first received 2 μg of endotoxin (55 animals), the second 20 μg (49 animals) and the third (111 animals) 200 μg. Half of each of the above groups received four daily injections of 18 mg of 6-MP/kg body-wt. beginning at the time of antigen injection while the other half received four daily injections of the diluent solution, thus serving as controls.

The results of these experiments are given in Table 1. Each 6-MP treated group had significant reduction in titre when compared to its respective control ($P < 0{\cdot}01$ for each, *t* test). Antibody titres of sera from both control and drug-treated rabbits were greater for the higher doses of antigen. However, the immunosuppressive action of the drug was not greater as the dose of antigen was increased ; this finding is clearly different from those with tanned red cells and bovine serum albumin as antigens[2,3]. In fact, if anything, there was a tendency toward less-pronounced suppression at the highest dose-level, 200 μg. The differences of the means of the three groups were tested for homogeneity using the *F* test, and the results were $F = 0{\cdot}7$, $P > 0{\cdot}25$.

Table 1. EFFECT OF DOSE OF ENDOTOXIN ON ANTIBODY LEVELS IN 6-MP-TREATED RABBITS

Dose of endotoxin (μg)	Drug	Antibody titre
2	6-MP*	4·2† (2·6–6·8)‡
2	Control	16·0 (10·6–24·3)
20	6-MP	9·4 (6·0–15·0)

* 18 mg/kg of 6-MP daily for 4 days.
† Geometric mean reciprocal titres.
‡ Parentheses equal 95 per cent confidence limits.

While the results of the work recorded here are clear, it would not be logical to generalize from the effects of 6-MP on this immunologic system. It has recently been reported that 6-MP is capable of suppressing the development of 7*S* γ-globulin antibody to bovine γ-globulin but not 19*S* macroglobulin antibody to this antigen[7]. This work illustrates the hazards of generalizing from a single system, since the typical antibody produced in response to this dose of endotoxin is of the 19*S* variety and the suppressive action of 6-MP is readily manifested[4].

The differences between the present results and those previously reported[2,3] are probably due to the type of antibody response elicited by endotoxins. Both the previous reports of enhanced suppression by 6-MP with increasing doses of antigen were concerned with primary immune responses. Since normal rabbits have 'natural' (that is, bactericidal) antibodies to most endotoxins, including that used in these investigations, the elicited antibody responses are perhaps of the secondary type. Another possible explanation of the described effects is the distinctive character of the polysaccharide antigens when compared with that of proteins. That the results reported in these studies are probably typical for this category of complex polysaccharides is attested to by the fact that 6-MP will suppress the antibody response to the antigens of *S. enteriditis* and *Escherichia coli*[4]. Work on antimetabolites may thus help to delineate differences in immune response to different types of antigen (that is, protein versus polysaccharide) as well as the characteristics of primary and secondary immune responses.

We thank Messrs. S. B. Ward and J. Edelin for their assistance and Dr. D. W. Alling for the statistical analyses. The 6-mercaptopurine was generously supplied by Dr. G. H. Hitchings, Burroughs Wellcome Co.

Permeability Factor in Pollen Extracts Active in Non-sensitized Mice

MOST of the recent work on hypersensitivity to pollens has been concerned with the isolation and characterization of the pollen allergens. The presence of biologically active materials in pollens, other than allergens, has been overlooked. The results presented here, however, demonstrate that pollen extracts contain a factor which increases vascular permeability in normal non-sensitized mice. Permeability factor was first detected by injecting Swiss Webster 20 g female mice intravenously with a mixture

Table 1. ATTEMPTS TO PRODUCE INCREASED VASCULAR PERMEABILITY IN THE EARS OF MICE BY INJECTING THE ANIMALS INTRAVENOUSLY WITH 0·2 ML. OF 0·5 PER CENT EVANS BLUE DYE AND VARIOUS AGENTS

* Maximal blueing occurred within 15 min and persisted for days.

† Maximal amount that could be tested due to the toxicity of the preparation.

‡ Approximate ED_{50}.

of 0·1 ml. of rye grass pollen extract and 0·2 ml. of 0·5 per cent Evans blue dye. Five min after the administration of dye plus pollen, a few blue spots appeared near the base of the ears; within 15 min large areas of the surface of the ears appeared deep blue. Control animals injected with dye alone showed no blueing of the ears. The most active batch of permeability factor (ED_{50} 20 μg) has been prepared from Italian rye grass (*Lolium multiflorum*). The permeability factor is precipitated from an aqueous extract of this pollen by ethanol containing 6 per cent potassium chloride. The permeability factor present in alcohol-precipitable *Lolium* is a non-dialysable very stable material. Its permeability promoting activity is unaffected by treatment with the following agents: boiling water for 30 min; 8 M urea, 4 h; conc. ammonium hydroxide, 1/2 h; α-amylase, 37° C, 4 h; pronase, 37° C, 4 h. Lyophilized preparations of alcohol-precipitable *Lolium* have retained their activity for months. The data in Table 1 compare the permeability enhancing ability of alcohol-precipitable *Lolium* with that of known permeability factors using the ear blueing technique. It can be seen that blueing did not occur in mice injected with dye plus one of the following: bradykinin, *E. coli* endotoxin (Difco), *Crotalus atrox* venom, and trypsin. Ear-blueing occurred in mice sensitized with bovine serum albumin and afterwards challenged with bovine serum albumin, as well as in mice injected with dye plus either of the following: serotonin, histamine, or 48/80. Serotonin produced a marked blueing within seconds after its administration, while the blueing produced by histamine was faint and diffuse. After the injection of 300 μg of alcohol-precipitable *Lolium* the histamine content of the ears of mice dropped from 150 μg/g to 40 μg/g. Ear-blueing was inhibited by 10 μg of the antihistamine 'Neoantergan' or 50 μg of the antiserotonin drug '*UML* 491' (Sandoz). Although an antihistamine inhibits ear-blueing due to alcohol-precipitable *Lolium* in normal mice, it does not inhibit ear-blueing produced in bovine serum albumin-sensitized mice challenged intravenously with bovine serum albumin. It thus seems unlikely that ear-blueing from alcohol-precipitable *Lolium* is due to the presence of antibodies to alcohol-precipitable *Lolium* in the sera of normal mice. No hæmagglutinating antibodies to alcohol-precipitable *Lolium* have been found in the sera of normal mice, and the incubation of alcohol-precipitable *Lolium* with normal mouse serum prior to its injection does not result in neutralization of the ability of alcohol-precipitable *Lolium* to increase vascular permeability.

Preparations of alcohol-precipitable *Lolium* contain pollen allergens as well as permeability factors. Allergenic activity is demonstrated by the ability of alcohol-precipitable *Lolium* to induce passive cutaneous anaphylaxis in mice injected intradermally with a mouse antiserum to rye grass pollen. Thus far it has not been possible to separate the permeability factor from the components of alcohol-precipitable *Lolium* which are allergenic in mice. Treatment of alcohol-precipitable *Lolium* with acid, alkali, heat, enzymes, 8 M urea, etc., has affected allergens and permeability factors in a similar manner. Chromatographic fractions of alcohol-precipitable *Lolium* obtained from DEAE and DEAE-'Sephadex' columns gave positive biuret and orcinol reactions and produced both blueing of the ears and positive passive cutaneous anaphylactic reactions. It is known that grass pollen allergens are polypeptides with a high carbohydrate content[1], and it is possible that the permeability-promoting activity of alcohol-precipitable *Lolium* resides in molecules of a similar composition. Sehon and Richter[2] have suggested that complexes of pollen allergens are continually breaking down during fractionation. The permeability factor may have indeed been produced by such a process. The presence of a permeability factor in rye grass pollen which acts by releasing histamine suggests that 'specific' desensitization to pollens in man may to some extent be a non-specific procedure dependent on the induction of tissue refractoriness to histamine. Feinberg *et al.*[3] demonstrated that the repeated injection of 48/80 in human skin resulted in a local refractoriness to the allergic response to ragweed or grass pollen.

The role of permeability factors in the unreliability of skin tests to pollens in humans has not yet been determined. Alcohol precipitable *Solium* will increase vascular permeability when injected directly into unsensitized mouse skin (ED_{50}, about 50 μg). However, it must be admitted that this dose far exceeds the amounts needed to produce a positive skin test in an allergic individual.

Immunofluorescent Detection of Proliferating Human Antibody-forming Cells

DIFFUSION chamber cultivation studies with human lymph-node tissues have shown a high proliferative activity of the immune cell population immediately before and during antibody production as indicated by the incorporation of tritiated thymidine *in vitro*[1]. It became of interest, therefore, to determine the proliferative capacity of the antibody-containing cells as compared with the cells in the same population which were not forming antibody. This was done by using both *in vitro* and *in vivo* exposure of the cultivated cells to tritiated thymidine and subsequent staining of the cells for antibody by immunofluorescence followed by autoradiography.

Human lymph-node cells stored at liquid nitrogen temperatures and known to have the capacity to form antibody to *S. typhosa* antigen by previous tests[2] were used for this investigation. Nucleated cells obtained from storage were thawed and washed 3 times with Medium 199 to remove the preservative, dimethyl sulphoxide. They were then incubated *in vitro* with *S. typhi* antigen in a cell : antigen ratio of 1 : 2. Aliquots of this mixture containing 10×10^6 lymph-node cells were placed in diffusion chambers for subsequent cultivation in X-irradiated (600 r.) mice. One group of chamber recipients was injected with 4 doses of 5 μc. of tritiated thymidine intraperitoneally, beginning 6 days after implantation and at 12–24 h intervals over a period of 2·25 days. These intervals of injection were chosen because it had previously been observed that antibody is not detected in the chamber fluid in this system until day 7 and that the blast cells reach their peak at 6 days after cultivation[2]. A second group received no *in vivo* exposure to tritiated thymidine, but the cells obtained from these chambers at the time of removal were incubated *in vitro* with 0·5 μc. tritiated thymidine for 1 h at 37° C. The animals in each group were killed at 10, 11, and 12 days post-treatment, chamber fluid was recovered, and the cells were stained with immunofluorescent reagent. Immunohistochemical staining was performed by the double-layer technique[3] as follows: Cells from the chambers were smeared over a 10-mm diameter in the centre of a glass slide with a Pasteur pipette, air-dried, and fixed in acetone for 15 min. A drop of a 0·03 per cent flagellin solution *p*H 7·0 extracted from the flagella of *S. typhi* cultures was placed on the cells and the slide was incubated in a moist chamber for 45 min at 25° C. (The extracted flagellin protein from typhoid H flagella was kindly supplied by Dr. Frank F. Fitch, Medical School, University of Chicago.) The slides were washed in 0·01 M phosphate buffered saline *p*H 7·2 and then layered for 45 min with 1 drop of a globulin fraction of serum, which had been obtained from rabbits hyperimmunized with multiple injections of *S. typhosa* vaccine and conjugated with fluorescein isothiocyanate according to the method of Riggs *et al.*[4]. The conjugated reagent had been absorbed twice with mouse liver and spleen powder immediately before use to avoid non-specific staining. The slides were washed as before, mounted in 0·01 M phosphate buffered glycerol *p*H 7·2, and observed for fluorescence with the standard Zeiss fluorescence microscope. After immunofluorescent treatment, autoradiograms of the cells were made with exposures of about 1 week and then stained with Giemsa[5].

Table 1. FREQUENCY OF TRITIATED THYMIDINE (^{3}HT) INCORPORATION BY HUMAN ANTIBODY-FORMING LYMPH-NODE CELLS CULTURED IN DIFFUSION CHAMBERS IN X-IRRADIATED (600 r.) MICE AFTER *in vitro* AND *in vivo* EXPOSURE TO TRITIATED THYMIDINE (^{3}HT)

Time after *Ag* stimulation (days)	*In vitro*			*In vivo*		
	$\log_2$ titre*	^{3}HT-positive *Ab* cells (%)	Total ^{3}HT-positive cells (%)	$\log_2$ titre*	^{3}HT-positive *Ab* cells (%)	Total ^{3}HT-positive cells (%)
10	9	14·3	2·0	4	75·0	18·6
11	9	—	0·7	8	87·5	32·5
12	9	0·0	0·7	10	92·3	30·8

* Titration of chamber fluid involved 2-fold serial dilutions in 0·1 ml. saline, addition of 0·1 ml. typhoid *H* antigen, incubation at 56° C for 2 h in a water bath and at 4° C for 18 h. Titre is expressed as the $\log_2$ of the reciprocal of the highest dilution giving visible agglutination.

Ab = antibody; *Ag* = antigen.

All chambers had fluids that were positive for agglutinins against typhoid *H* antigen and yielded cells the cytoplasm of which stained a brilliant green with the immunofluorescent reagent, indicating the presence of precipitating antibody against the extracted protein of typhoid *H* flagella antigen in the cells. Subsequent autoradiographic analysis of the cells showed that not only were antibody-containing cells capable of incorporating the radioactive compound in their nuclei after *in vitro* incubation at 10 days, but also that they did so at a higher frequency than the cells of the total population, the frequency being 7 times greater in the antibody-containing cells (14·3–2 per cent) (Table 1). At 12 days, however, none of the antibody-containing cells incorporated tritiated thymidine, this being comparable to the amount of incorporation (0·7 per cent) seen in cells of the total population at the same time interval. After *in vivo* exposure to the radioactive compound the frequency of tritiated thymidine labelling in the antibody-containing cells increased from 75 to 92 per cent on days 10–12 and was 3–4 times greater than the cells of the total population (Table 1). Fig. 1 shows a representative human antibody-forming cell labelled with tritiated thymidine.

These results indicate: (*a*) that the competent human antibody-containing cells proliferate at a greater frequency than the incompetent cells during the early phases of antibody synthesis and that the rate of proliferation is reduced to normal levels during the later phases of the antibody response; (*b*) that these mature antibody-containing cells are derived from precursor cells through somatic division. These findings are compatible with those of Urso and Makinodan[5], who used the rabbit anti-BSA : BSA system with pre-immunized spleen and lymph-node cells cultured in diffusion chambers. The present investigation shows that the diffusion-chamber technique in conjunction with immunofluorescent analysis is feasible for studying cellular dynamics of human antibody-forming tissue after stimulation with an antigen.

RADIOBIOLOGY

Effect of Chemical Protective Agents (Cysteamine and β-Aminoethylisothiuronium (AET) Cl HCl) and Homologous Testes-DNA on the Death-rate of the Progeny of a First Generation originating from Male Rats irradiated in the Infantile Period

It is well known that irradiation causes death of the progeny of adult irradiated animals. For example, Osipovskii[1] found that the death-rate of the progeny of males irradiated with an X-ray dose of 360 r. reaches 53 per cent. Hertwig[2] found that the percentage of dead progeny in the period from their birth to the seventy-fifth day of age is considerably higher than later. Strandskow[3] also found an increased death-rate in the progeny of irradiated male guinea pigs for the period up to 30 days of age. Henson[3] also observed the death-rate of the progeny of male rats irradiated with an X-ray dose of 100–1,000 r. during their lactation period. It has been found that 46 per cent of the progeny live until the end of the lactation period. Observing the changes on the progeny of male mice irradiated with 25 MeV through five generations, Proshina[4] found the highest death-rate in the first generation and in the first month of life.

In our experiments, Wistar male rats were X-irradiated in the infantile period (8 and 17 days old) with a dose of 600 r. and mated with normal females when they became sexually matured. The death-rate of the progeny of the first generation was observed up to four months of age. The percentage of deaths of the progeny of normal parents observed in the course of one year was 3 per cent.

The death-rate was observed in the progeny of males: (*a*) irradiated with 600 r.; (*b*) treated with cysteamine and irradiated; (*c*) treated with AET and irradiated; (*d*) irradiated and treated with homologous testes-DNA.

The results are shown in Fig. 1.

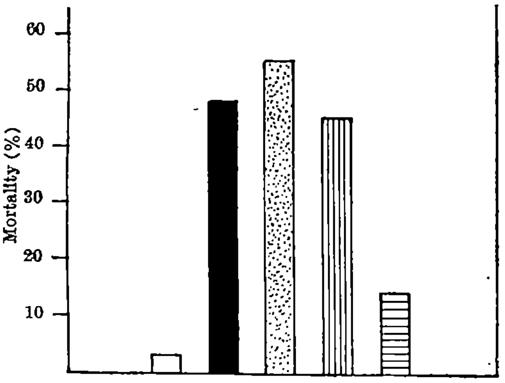

Fig. 1. Death-rate of the progeny of the first generation

Number of the progeny observed: 130 irradiated with 600 r.; 184 treated with cysteamine and irradiated; 185 treated with AET and irradiated; 326 irradiated with 600 r. and treated with homologous testes-DNA

White, normal; black, controls; stippled, cysteamine; vertical hatching, AET Cl HCl; horizontal hatching, DNA

Fig. 1 shows a high percentage of deaths in the progeny of males irradiated in the infantile period mated with normal females, namely, 48 per cent of irradiated males; 55 per cent of males protected with cysteamine before irradiation; 45 per cent of males protected with AET before irradiation; 14 per cent of males treated with testes-DNA after irradiation.

Sometimes it happens that all the animals of the litter die and sometimes only some of them. Autopsy did not reveal the cause of death. It was noticed that the main progeny which died were dwarfs.

If the death of the progeny of irradiated animals and those protected with chemical agents in the F_1 generation is considered to be the result of dominant lethal mutations, then our results show that neither cysteamine nor AET can prevent the occurrence of mutations, which in the F_1 generation are expressed as dominantly lethal. The results obtained in this respect are contradictory. Namely, examining cysteamine, Kaplan and Lyon[5] found that it does not influence the induction of dominantly lethal mutations in different post-meiotic stages. On the other hand, Lüning and Frölen[6] show that cysteamine can be a protective agent against genetic injury because it reduces the death-rate in the post-implantation period.

In addition, our results show that testes-DNA reduces the percentage of deaths and the values are closer to normal.

In vivo Migration of Colony-forming Units from Shielded Bone Marrow in the Irradiated Mouse

The early bone marrow and spleen shielding experiments of Storer[1], Kaplan[2] and Jacobson[3] first indicated that hæmatopoietic stem cells were capable of migration and repopulation of X-irradiation depleted hæmatopoietic tissues. Popp[4] and Goodman[5] then showed that buffy coat obtained from the peripheral blood of mice contained cells capable of producing mature erythrocytes, lymphocytes and granulocytes. Trobaugh[6] has recently demonstrated that peripheral blood of the mouse contains cells capable of forming colonies in the spleen of irradiated recipients. He finds peripheral blood contains about 1 per cent of the number of colony-forming units (CFU) found in bone marrow, when comparing total nucleated cells injected. Hellman[7] reports granulocyte counts in the peripheral blood of the mouse recovered more slowly when partial body irradiation is given during 2 h, when compared with similar dosage delivered in a few minutes. He concludes this is due to killing of circulating stem cells.

Utilizing the ability of stem cells to form nodules in the irradiated spleen as initially shown by McCulloch and Till[8], combined with short-term shielding of a portion of the bone marrow, it has been possible to obtain a more quantitative estimate of the rate of release of stem cells to the circulating blood in the thigh shielded irradiated mouse, and to determine the changes in this release process following sub-lethal whole-body irradiation.

Two separate experiments were performed with each of two inbred strains. These were 8–10-month-old retired *L* female breeders and 14–16-week-old *LAF*-1 females. In the first experiment, groups of mice were anæsthetized with intraperitoneal pentobarbital and given 900 r. whole-body irradiation with an 8-mm wide, 1·5-mm thick circular lead thigh shield held in place by masking tape. At times of 2–7 h later the mice were again anæsthetized and given 900 r. to the shielded extremity. Eight days following irradiation, survivors were killed and their spleens removed and fixed for counting of nodules with the aid of a dissecting microscope.

In the second experiment, the mice were anæsthetized and given 300 r. whole-body irradiation with a 16-mm wide lead thigh shield in place. Approximately 48 h later, they were again anæsthetized and given 800 r. whole-body irradiation with an 8-mm wide lead thigh shield in place. Two to 3 h later they were given 900 r. to the shielded extremity, then maintained for 8 days after which their spleens were gathered for nodule counting. The larger thigh shield was used initially to avoid misplacement of the thigh shield used in the second part of the experiment. Irradiation factors were 250 kVp, 35 cm TSD, 1·28 mm copper, half-value layer, 225 r./min.

Bone marrow was thoroughly removed from 7-mm sections of femur that corresponded to the area shielded in the irradiated groups. Twenty femurs obtained from ten 15-week-old *LAF*-1 female mice, and twenty from ten retired *L* female breeders, were examined. The 7-mm segments of these were found to contain a similar mean of $1·9 \times 10^7$ nucleated cells (*L* female range $1·2 \times 10^7$–$2·7 \times 10^7$, *LAF*-1 female range $1·5 \times 10^7$–$2·4 \times 10^7$).

Fig. 1 shows the number of spleen colonies counted 8 days after a portion of the thigh was shielded for an interval of between 1 and 7 h in lethally irradiated adult *L* female mice. The mean for each time interval is plotted; the bar includes two standard deviations, and the total number of spleens used in determining a point is given in parenthesis. The control value of 0·3 nodules per spleen is also shown. This plot indicates that approximately 1·8 CFU appear in the spleen during each hour following thigh shielding, up to a total of 7 h.

Fig. 2 is a similar plot of the results obtained in young adult *LAF*-1 female mice. The control count of 0·2 nodules is indicated. This rate of CFU appearance in the spleen also appears to be constant at approximately 1·9 CFU/h of exposure to shielded thigh bone marrow.

Fig. 3 indicates the values obtained for CFU migration to the spleen from the bone marrow of a shielded thigh 48 h after an initial dose of 300 r. whole-body irradiation. The values for *L* female and *LAF*-1 female mice are combined. The rate of appearance of CFU in the spleen is 1·6 nodules/h of exposure to shielded thigh bone marrow.

The *in vivo* migration of stem cells in the normal and irradiated mouse is well established. The rate of migration to the spleen from a shielded population of $1·9 \times 10^7$ nucleated marrow cells is constant during the first 7 h following whole-body irradiation, and is the same for the two strains of mice tested. The rate of release of CFU to the circulating blood from shielded marrow does not appear to have changed 48 h after an initial whole-body dose of 300 r. This implies that repopulation of irradiation-depleted bone marrow sites in the partially shielded mouse is not the result of increased release of stem cells by the shielded area.

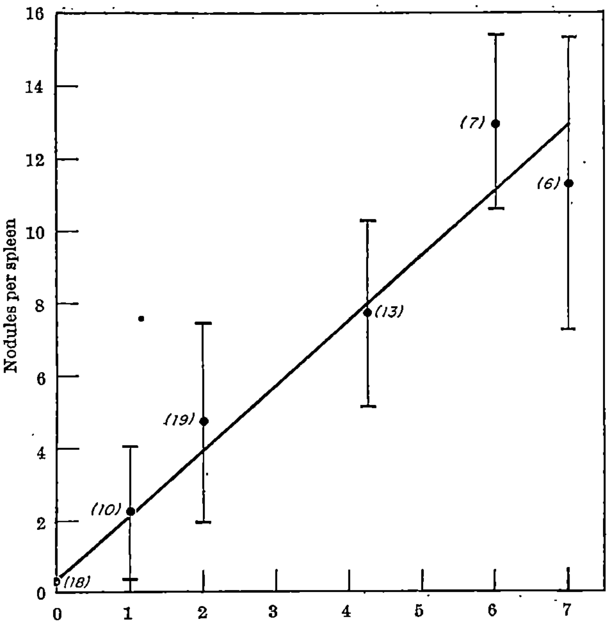

Fig. 1. Spleen nodules eight days after thigh shielding for various time intervals in lethally irradiated *L* female mice

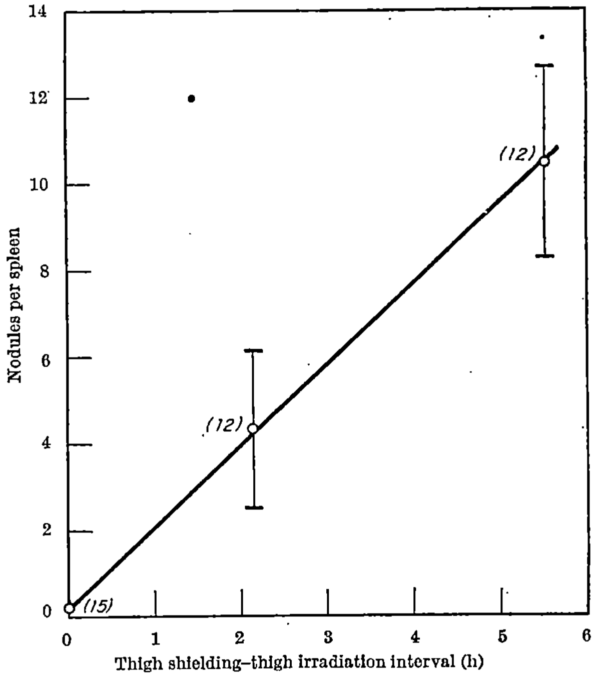

Fig. 2. Spleen nodules eight days after thigh shielding for various time intervals in lethally irradiated *LAF*-1 female mice

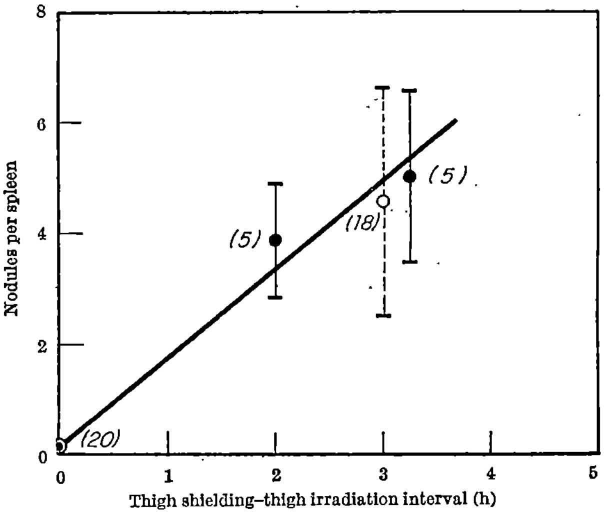

Fig. 3. Eight-day spleen nodules formed after thigh shielding for various time intervals, 48 h after 300 r. sub-total whole-body irradiation in lethally irradiated *L* female (●) and *LAF*-1 (○) female mice

There are two possible sources of error in determining these rates of release. The thigh shield used was not sufficient to attenuate the beam totally (4 per cent transmission) and the portion of shielded marrow that received side scatter cannot be calculated. Both these would result in migration rates lower than actually exist for a given shielded population. The values of 1·8 and 1·9 CFU/h for approximately $1·9 \times 10^7$ shielded cells must be regarded as minimum estimates.

The estimated shielded population is about 5 per cent of the total hæmatopoietic tissue. This means that for the total bone marrow 36 CFU would migrate to the spleen per hour. The only result available estimating the proportion of injected cells which settle in the spleen is that of McCulloch and Till[9]. They found that 1/6 of the injected CFU appeared in the spleen. If this proportion applies to the *in vivo* migration of CFU, it would indicate that more than 200 CFU enter the peripheral blood during any given hour.

Female *LAF*-1 mouse bone marrow contains 11 CFU per 10^5 nucleated cells[10], a value in good agreement with those reported by McCulloch and Till[11] for several other strains. Calculations from these results indicate that 1·9 × 10⁷ nucleated marrow cells would contain about 2,100 spleen CFU. Calculating from the percentage of injected CFU that settle in the spleen, it indicates this marrow population contains a total of about 12,600 CFU. The data show 1·8 spleen colony-forming units are released from this pool per hour, or 43 a day. The same calculation of CFU released but not deposited in the spleen indicates that a total of about 250 CFU (2 per cent of the marrow CFU content) enter the circulating blood each day.

Colony-forming units released *in vivo* by the bone marrow are expected to have considerable mechanical advantage for free circulation over cells injected in a single bolus. They will also be free of the damage which must accompany preparation and injection of single cell suspensions *in vitro*. This may result in a greater efficiency of viable colonization of the spleen, with corresponding changes in the estimates of total CFU entering the circulation per unit time, and the percentage of marrow CFU circulating during a 24-h period.

Artefactual Chromatid Aberrations in Untreated and X-ray-treated Human Lymphocytes

RECENTLY, there has been a disquieting number of reports of observations of chromatid aberrations in human lymphocytes as a result of various treatments and conditions varying from measles to X-ray[1–4]. Although there has been no good reason to doubt the nature of these chromatid aberrations, neither has there been a good test of whether or not their induction could be attributed to phenomena other than the agents indicated in the various reports.

During an investigation of the relative *in vivo* radiosensitivity of the chromosomes of infants we observed chromatid aberrations in the chromosomes of their cultured lymphocytes following diagnostic X-ray procedures. These observations afforded us the opportunity for testing the interpretation of these and other similar reported observations as well as the relative sensitivity of the chromosomes of infants.

All chromosome investigations were carried out on samples of capillary blood using an adaptation of the method of Moorhead[5]. Replicate specimens were examned whenever possible and preparations were analysed n respect of numbers of cells containing chromosomal aberrations and the type of aberration, chromosome or hromatid.

Table 1 represents the results of the primary observaions on the chromosomes of infants following diagnostic X-ray procedures which included chest films, cinecystourethrogram, angiocardiogram and aortogram with a dosage range of approximately 2–20 r. The predominant aberration type observed was the chromatid deletion as seen in Fig. 1.

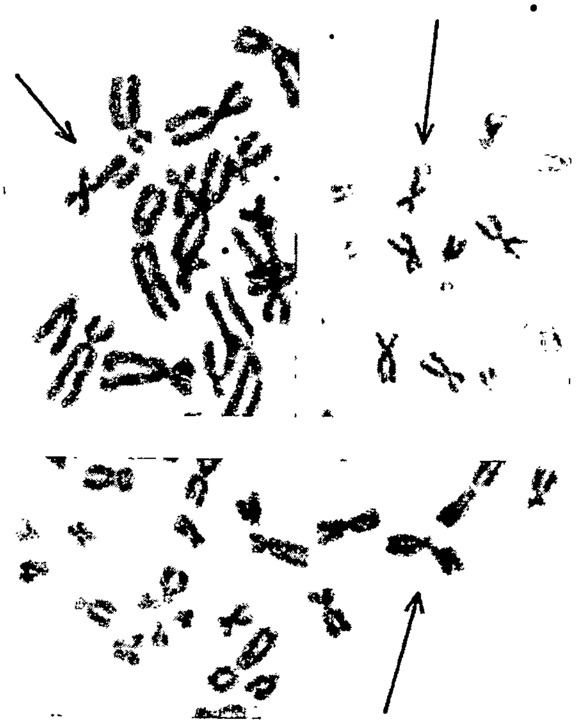

Fig. 1. Chromatid aberrations from metaphase lymphocytes from irradiated infants

A group of infant controls (Table 2) evidenced no comparably high frequency but showed considerable variability, ranging from 1·6 to 8·0 per cent. A subsequent examination of adult controls (Table 2) also showed considerable variability and, in addition, high frequencies of chromatid aberrations.

Three things are immediately obvious: (1) The frequencies of chromosomal aberrations in the X-rayed infants (Table 1) are higher than one might expect for the dosage of X-ray received[6,7]. (2) There are considerable numbers of aberrations in the control groups (Table 2) especially among the adults. (3) The predominant aberration type, the chromatid deletion, is totally unexpected, since previous investigations using tritiated thymidine[8] have demonstrated that, in adults, circulating lymphocytes are in a mitotic stage prior to DNA synthesis, that is, G_1. It is at this stage that we would expect the induction of chromosome type aberrations in cells exposed to X-ray[9]. One can explain the observation of chromatid deletions

Table 1. CHROMATID ABERRATIONS IN LEUCOCYTE CULTURES FROM IRRADIATED INFANTS

Subject	Approximate X-ray dosage (r.)	Cells scored	Chromatid type aberrations (%)
Infant 1, 13 days (♂)	20	313	24·3
Infant 2, 2 months (♂)	20	211	19·9
Infant 3, 5 weeks (♀)	Pre X-ray	130	16·9
	18	82	35·4
Infant 4, 10 days (♀)	Pre X-ray	125	4·8
	2–4	151	7·9

Table 2. CHROMATID ABERRATIONS IN LEUCOCYTE CULTURES FROM UNIRRADIATED, HEALTHY NEW-BORNS AND ADULTS

Subject	Cells scored	Chromatid type aberrations (%)
Infant 5, 5 days (♂)	64	1·6
6, 1 day (♀)	57	7·1
7, 3 days (♀)	37	2·7
8, 1 day (♂)	102	4·9
9, 2 days (♀)	150	8·0
Adult 1, 30 yr. (♂)	49	10·2
2, 40 yr. (♂)	100	12·0
3, 23 yr. (♀)	51	21·6
4, 32 yr. (♀)	95	17·9

in two ways: either they are artefacts or they are derived from cells representing a population of cells, which, in infants, are in G_2, that is, subsequent to DNA synthesis. The presence of chromatid deletions in the adult controls tends to negate the latter argument for reasons presented here. Nevertheless, it is not a satisfactory demonstration that no substantial population of lymphocytes, in infants, is in a stage subsequent to DNA synthesis.

To examine this possibility, we offered tritiated thymidine (specific activity 6,000 μc./mM in a concentration of 1 μc./ml. of media) to the cultured lymphocytes of both infants and adults for 1 h at various times (48, 54, 64 h) following incubation. In both infant and adult more than 90 per cent of the interphase nuclei and metaphases showed evidence of thymidine uptake. In addition, infant lymphocytes were not sufficiently different from adult in rate, amount or timing of uptake to support any theory that they are in fact different. This demonstrates clearly that the majority of lymphocytes of the infant had not reached the G_2 period prior to incubation. Therefore, the chromatid deletions that we have observed were most probably not induced by X-ray treatment, nor were they likely to be induced in lymphocytes by any other previously implicated agent prior to the initiation of leucocyte culture, nor for 48 h following the initiation of culture.

Table 3. CHROMATID ABERRATIONS IN HUMAN LEUCOCYTE CULTURES IRRADIATED *in vitro*

		Cells scored	Chromatid type aberrations (%)	Chromosome type aberrations (%)	Iso. frag. (%)
Adult (♂)	30 r. G_1	100	9	—	—
	30 r. G_2	100	14	—	—
Adult (♀)	30 r. G_1	100	5	—	—
	30 r. G_2	100	15	—	—
Infant (♂)	30 r. G_1	50	14	—	2
	30 r. G_2	100	19	—	—
Infant (♀)	30 r. G_1	100	11	—	2
	30 r. G_2	200	17	—	4

A further demonstration of the artefactual nature of the chromatid deletions which we have observed is presented in Table 3. These are the results of an *in vitro* investigation of cultured lymphocytes of both adults and infants which have been exposed to 30 r. prior to incubation, and 5 h prior to gathering. These stages we designate G_1 and G_2 respectively on the basis of our tritium investigations and those of German[8]. In G_1, where no chromatid type deletions would be expected, there is a frequency constantly present but consistently lower than that in G_2, the stage in which chromatid aberrations would be expected to be induced. Consequently, the frequency of chromatid aberrations seen in G_1 must be interpreted as background and considered as a constant threat to the interpretation of these kind of results.

It should also be noted at this point that all the evidence indicates that there is no difference in relative radiosensitivity between lymphocyte chromosomes of four-day-old infants and forty-year-old adults, all of which exhibit a reasonably high sensitivity to insult by irradiation.

An investigation of the origin of the background aberrations is being completed at the time of writing. The exact process is as yet unknown; but they are probably initiated by technical procedures. Their presence in the absence of adequate controls should not be considered sufficient evidence of a response to previous insult by any agent. Moreover, merely showing localization of the breakage to specific areas of specific chromosomes does not lend credence to the observation since sensitivity to mechanical stress can be just as specific and may be the result of differential coiling and/or heterochromatic areas.

The kind of chromatid aberrations which can be differentiated from background and were never seen in the unirradiated control population were chromatid exchanges and iso-chromatid deletions with sister chromatid reunion. Assay of these aberration types provides much more reasonable evidence of treatment-induced damage.

BIOLOGY

Effect of a Diet containing Sodium Deoxycholate on the Intestinal Mucosa of the Mouse

THE life-span of the mucosal cell of the intestinal villi is short; reported values range from about 1 to 2 days depending on the region and the species examined[1-5]. Neither the reasons for the extremely short life-span nor the factors that influence the life-span are understood.

For many years the importance of bacteria as a factor in the rate of intestinal cell attrition has been discussed. Dixon[6] demonstrated the importance of peristalsis in flushing the intestinal flora towards the cæcum. Paulley and Dixon[7] found that a period of reduced peristalsis, induced by injections of mecamylamine, resulted in partial denudation of the upper intestine. Abrams *et al.*[8] and Lesher *et al.*[9] have shown that the life-span of the intestinal cells is about twice as long in the germ-free mouse as in the conventionally raised mouse. However, it is not known how the presence of bacteria reduces the life-span of the cells.

Although the detergent properties of the bile acids have been known for a very long time, their possible role in influencing the rate of cell turn-over in the intestine appears to have been neglected. It is perhaps significant that the ileum, which is the site of absorption of the conjugated bile acids, is the region of the small intestine in which the mucosal cells have the shortest life-span. Of greater importance, particularly in relation to clinical conditions, is the fact that highly detergent and cytotoxic substances such as deoxycholic acid are produced in the intestinal tract by the microbial action on the conjugated bile acids. Norman and Grubb[10] showed that certain members of the intestinal flora hydrolysed the conjugated bile acids and that this occurs mainly in the cæcum. In the germ-free animal and with neomycin treatment deoxycholic acid is not produced[11,12].

While it has been shown that *in vitro* incubation with deoxycholic acid caused marked damage to the villi[13], and Sullivan demonstrated the importance of the bile acids in post-irradiation diarrhœa[14] and the release of mucin from goblet cells, there is little information on the *in vivo* effects of varying the quantity or type of bile acid in the diet. The preliminary results of an investigation of the effects of feeding mice a diet containing sodium deoxycholate are reported here.

BCF$_1$ mice, about 100 days of age, were maintained on: (1) a synthetic diet (casein, 18 per cent; corn oil, 10 per cent; sucrose, 68 per cent; salt mixture No. 2, U.S.P., 4 per cent; complete vitamin fortification mixture, Nutritional Biochemicals Corporation); (2) the same diet with 2 per cent sodium deoxycholate added. Mice were kept under observation for more than one month, and were killed at 2, 8 and 39 days after starting the diet. The mice fed the control synthetic diet showed no gross or microscopic changes. Mice in the experimental group appeared sick within two days; they were listless and their fur was ruffled. Two days later the mice were active and appeared normal except their fur was now oily. This change in the appearance of the fur gradually disappeared in about three weeks.

At death on the second day the upper intestine was more translucent and thinner than normal. The gall bladder was distended and at least three times the normal size. At eight days the gross appearance of the lower intestine was similar to that of the upper intestine at the early death interval. There was a striking hyperæmia of the entire length of the small intestine, but otherwise the appearance of the upper intestine was almost normal. The gall bladder was still markedly enlarged. At 39 days the intestine appeared normal, the gall bladder had decreased in size but the wall was thickened.

The microscopic appearance of the duodenal villi at the second day was abnormal (Fig. 2). There was separation of the mucosal cells from the underlying structures with œdema and proteinaceous material in the lamina propria. In the ileum at eight days there was partial denudation and a decrease in the number of goblet cells (Fig. 4). At later death intervals the appearance of the villi was almost normal and there was evidence of increased proliferation in the crypts. In the duodenum at three days there was an increase in the number of cells initially labelled with tritiated thymidine. There was marked increase in cell proliferation of the epithelium of the gall bladder. The results of the changes in cell proliferation will be published at a later date.

In general, the histological findings are similar to those reported by Nissim[15] on the effects of some surface-active compounds. We presume that the histological changes are due to the direct action of the deoxycholate on the surface of the mucosa. As the animals continue eating, the normal control mechanisms of bile flow presumably are active. Therefore, the marked increase in the size of the gall bladder is probably due to the choleretic effect of the deoxycholate.

In the germ-free animals no free acids are produced and conjugated bile acids are excreted. It has been found that the half-life of cholic acid was about five times longer than in the conventional animal[16]. The intestinal mucosa of the germ-free animal is exposed to less bile and to no bile acid metabolites and the life-span of the mucosal cells is considerably longer than in the conventional animal.

Fig. 3. Ileum of mouse on control diet (× c. 400)

Fig. 4. Ileum of mouse on diet containing 2 per cent sodium deoxycholate for eight days (× c. 400)

It seems a definite possibility that in conditions in which diarrhœa and partial denudation occur, and when no specific organism can be incriminated, the pathogenesis may be the following:

For some reason the motility of the gut is reduced; this results in a change in the distribution of the flora. The presence of sufficient numbers of bacteria capable of splitting the bile acids in the upper intestine results in amounts of metabolites that cause diarrhœa and in some cases damage to the mucosa. If these abnormal conditions were maintained for any length of time, steatorrhœa might occur because the amount of conjugated bile acids would be reduced due to the bacterial hydrolysis and the increased cell loss would add to the amount of fat in the lumen. Dawson and Isselbacher[11], and more anish[16], have suggested that the changes found he blind loop syndrome might be due to the production of bile salt metabolites by bacteria.

It is hoped that the use of the type of diet described will be useful for investigating the control of cell proliferation in both the mucosa of the small intestine and the gall bladder.

Extension of Mammary Glands to the Popliteal and Cubital Fossæ

THE development and histology of the mouse mammary gland have been studied in detail[1-3]. The glands develop along the milk line and branch in the subcutaneous fat between the skin and skeletal muscle. The quantity of fat in the subcutaneous fat pad is greatest where the milk ducts later develop[4]. During lactation the distribution of the mammary glands visibly follows the subcutaneous fat tissue, the second inguinal mammary gland being reported to spread only into the inguino-genital area and the cubital only to the level of the fore-limbs.

During histological examination of the popliteal lymph nodes of *C57*, *BALB*, *Ajax* and *Swiss* normal female mice, mammary gland elements were observed in the surrounding fat and this finding led to an examination of both the popliteal and cubital fossæ in lactating mice. Seven lactating mice two weeks after delivery and five non-pregnant, non-lactating females were studied; in addition, four males were also examined.

Tissues were fixed in Zenker-formol and embedded in paraffin ; sections were cut at 7μ and stained by hæmatoxylin-eosin ; however, alum carmine stain was utilized for the 100-200μ sections.

Gross observation during lactation showed that the first pectoral mammary gland extends into the cubital fossa, and that the second inguinal mammary gland extends into the popliteal fossa along the lateral posterior part of the femur (Fig. 1).

This observation becomes reasonable when it is noted that the cranial end of the subcutaneous fat pad extends into the cubital fossa and the caudal end into the popliteal fossa.

Besides the mammary glands, sebaceous and sweat glands can be seen, and these extend into the connective tissue of the sub-cutis layer above the connective tissue lamina.

Generally, when the skin is dissected from the muscles, sebaceous and sweat glands are removed with it. The structures found in the cubital and popliteal fat pads, however, remain on the muscle layer, that is, they are located in the subcutaneous fat pads below the connective tissue lamina and above the skeletal muscle. The sweat glands, moreover, are only seen in the palmar aspect of the paws.

In the lactating animals numerous tubulo-alveolar structures were observed in tissue from both fossæ, each being lined by large cuboidal epithelial cells (Figs. 2 and 3*A*). The epithelium contained numerous small vacuoles and stained an uneven purple, depending on the amount of secretory granules and RNA in the protoplasm. The nuclei were spherical in shape and stained rather lightly; each contained chromatin clumps and a nucleolus. The lumen contained an eosinophilic granular substance in the centre surrounded by foamy matter. The histological appearance is identical to that of the mammary gland in the inguino-genital area.

During lactation the mammary gland is directly surrounded by capillaries[5] or collagenous fibres, the latter sometimes being seen in the spaces around the tubulo-alveolar components. However, most of these spaces are occupied by lipid depleted fat cells[6]. In lactation the capillary bed between the fat tissues is also clearly seen and plasma cells are found in the walls of the capillaries. Plasma cells are rarely present, however, in the non-lactating animals.

In the non-lactating female group, similar tubulo-alveolar structures were also observed in the popliteal fossa (Fig. 3*B*) but not always in the cubital fossa. The mammary epithelium in such instances is much smaller and nuclei stain more deeply compared to those in the lactating group ; in addition, the longer axis of the nucleus parallels the surface of the lumen and the cytoplasm stains lightly with eosin. Homogenous eosinophilic substance is occasionally seen in the lumen. The tubulo-alveolar structures were surrounded by normal fat cells, each containing a single large fat vacuole ; in such cases there is no lipid depletion (Fig. 3*B*). Tubulo-alveolar structures were not observed in the four normal males examined.

The relationship in lactating mice between morphological activation of the mammary gland epithelium, lipid depletion and the appearance of plasma cells is interesting and finds certain parallels in stress. Selye and Timiras[7] have described the discharge of lipid from the brown fat tissue as a characteristic reaction during stress.

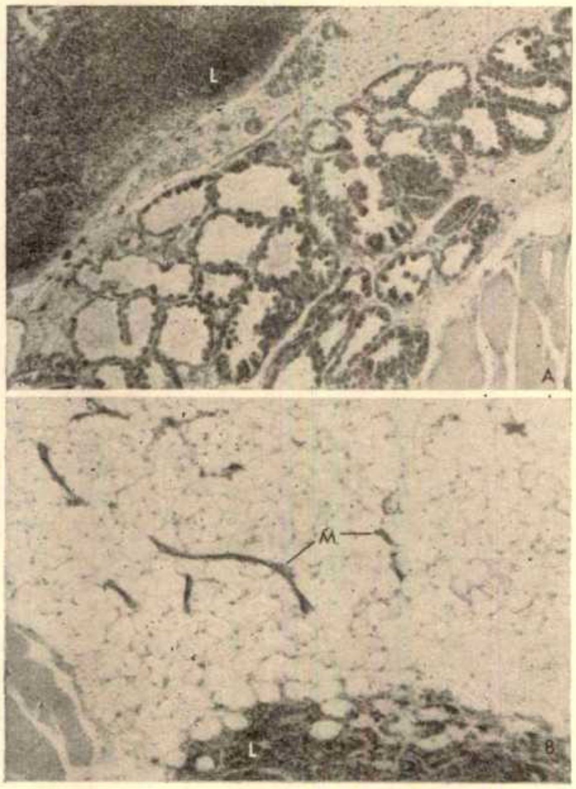

Fig. 3. (*A*) Mammary glands in the cubital fossa. Lactating mouse. *L*, lymph node. (× *c*. 66.) (*B*) Mammary glands in the popliteal fossa. Non-lactating female mouse. *L*, lymph node, *M*, mammary gland. (× *c*. 66.) Paraffin section fixed with Zenker-formol, stained with hæmatoxylin-eosin

White fat cells of mice show lipid depletion following persistent electric shock[8]; at the same time, plasma cell reaction and some activation of mammary gland epithelium are also seen[9]. This inverse relationship between plasma cell and fat cell in lactation and electric stress may be due, in part, to their common origin from the adventitial cells of the small blood vessels[10,11].

Trichostrongylus colubriformis (a Nematode Parasite of Sheep and Other Ruminants) as a Test Organism in Screening for Sheep Anthelmintics in the Laboratory

THE development of anthelmintic screening tests has been guided by the need for a laboratory model of the host–parasite system for which new anthelmintics are being sought. Up to the present time, use has been made of nematodes naturally parasitic in rats and/or mice.

We felt that a screening test using a sheep nematode as a test organism in a small laboratory animal host would be more relevant to finding a new sheep anthelmintic.

We have carried out a series of experiments on the host–parasite relationships of *Trichostrongylus colubriformis* in rats, mice, guinea pigs, rabbits and Libyan gerbils (*Meriones libycus*). The initial source of infective larvæ was a pure line strain maintained in sheep. The experimental animals were exposed to the infestation by oral intubation of suspensions of known numbers of infective larvæ.

Guinea pigs were found to vary greatly in their susceptibility to infestation; a finding in agreement with Herlich *et al.*[1], Herlich[2], and Sturrock[3]. Rats and mice were found to be very susceptible, but insufficient numbers of ova were recovered from their fæces to maintain the parasite indefinitely in these animals. Rabbits, as shown by El Rawi[4] and Wood[5], proved to be suitable hosts for the laboratory maintenance of the life-cycle and we have serially passaged the infestation through more than fifty generations during the past thirty months.

As rabbits are not ideally suited to screening large numbers of compounds, we investigated the infestation in rats and mice more fully with the view of establishing an anthelmintic screening test, and experiments were carried out to determine the optimum conditions for infesting rats and mice. Young male animals were found to be the most susceptible. The infestation lasted only three to four weeks and the maximum numbers of adult worms were recovered from the small intestine 14 days after inoculation. The optimum size of inoculum was found to be 1,000 infective larvæ per animal. On the basis of these data we devised anthelmintic screening tests using *T. colubriformis* as a test organism in rats and mice. Male rats (weighing 50 g) and male mice (weighing 20 g) were each given 1,000 infective larvæ. Twelve days after inoculation the animals were pooled and randomly divided into dose groups. The test compounds were administered orally in aqueous solution or suspension at a single dose of approximately three-quarters of the acute oral LD_{50}. Forty-eight hours after dosing the test animals were killed and post-mortem examinations were carried out. The first quarter of the small intestine was removed, inverted over a length of glass capillary tubing and wholly immersed in a test-tube of warm saline. The preparations were incubated at 37° C for 2 h during which time the worms detached themselves from the mucosa. The contents of the test-tube were emptied into a squared dish and the number of worms was counted under a dissecting microscope.

The mouse and rat tests were evaluated by comparing their responses to a number of known sheep anthelmintics. The rat test appeared to be somewhat more sensitive than the mouse test and was chosen for comparison with the anthelmintic screening tests in general use, namely, the *Strongyloides ratti*- and *Nippostrongylus braziliense*-rat tests and the *Oxyuris*- and *Nematospiroides dubius*-mouse tests. The techniques used were essentially those quoted by Standen[6]. Five reference anthelmintics were tested as if they were unknown compounds in each of the screening tests shown in Table 1.

The response to phenothiazine was negative in all but the *Oxyuris*-mouse test and even here the results were variable. The *S. ratti*-rat test failed to select bephenium and the *N. dubius*-mouse test missed thiabendazole.

We have used all the foregoing tests at one time or another in screening several thousand compounds for anthelmintic activity. Compounds active in any of these tests have been selected for testing in sheep. Only 59 compounds, however, have been tested so far in all five screening tests as well as in sheep. False positives are a common feature of screening tests and, although they may result in wasted follow-up work, they are not such serious deficiencies as false negatives. A false negative means that a useful compound has been missed. Eight of the 59 compounds were found to be active in sheep; of these eight, only two are of the same chemical series.

Results of tests in small animals with these compounds are shown in Table 2. From these results, both the *N. dubius*-mouse test and the *T. colubriformis*-rat test are more relevant than the other rodent screening tests in selecting anthelmintics for use in sheep, having one and two false negatives respectively. The *N. dubius* test, however, does not respond to thiabendazole (the best of the sheep anthelmintics) whereas the *T. colubriformis* test does. *T. colubriformis* and *N. braziliense* tests were found to be somewhat complementary. By using both organisms in the same rat, the number of false negatives was reduced to one, and the system was sensitive to thiabendazole.

Table 1

	Screening test activity:				
	v. *Oxyuris*	v. *N. dubius*	v. *S. ratti*	v. *N. brazil.*	v. *T. col.*
Bephenium	–	+	–	+	+
Phenothiazine	±	–	–	–	–

H	+	+	+	+	+	+	+

Table 2 also shows that no one test is completely satisfactory.

Preliminary investigations using the Libyan gerbil have shown that this animal is a suitable laboratory host for both *T. colubriformis* and *T. axei*. This host–parasite combination could be a further improvement in that both a sheep abomasal and a small intestinal worm could be maintained and used for screening in the laboratory.

We thank Miss J. Crowley for supplying the initial pure line larval culture and for carrying out the tests in sheep.

Circadian Control of Photoperiodism in the House Finch demonstrated by Interrupted-night Experiments

ALTHOUGH the reproductive cycle of many temperate zone birds is known to be dependent on photoperiod, the way in which birds measure the duration of the daily photoperiod is still uncertain[1]. In the house finch, *Carpodacus mexicanus*, testicular maturation can occur when birds are exposed to only 6 h of light in each cycle if the cycle durations are 12, 36, or 60 h, whereas no maturation occurs when the cycle durations are 24, 48, or 72 h[2]. These data appeared consistent with the hypothesis that a circadian rhythm of recurring phases of sensitivity to light is involved in the photoperiodic response[3]. If this is so, brief light periods administered during the darkness of non-inductive 24-, 48-, and 72-h cycles should also stimulate testicular maturation provided that the brief light periods are in appropriate relation to the basic circadian rhythm. Indeed, although the interpretation of interrupted-night experiments with animals has been controversial, recent experiments with plants show that flowering can be controlled by brief light periods in such a manner[4]. The following experiments, therefore, were designed to test the hypothesis of circadian control by exposing birds to non-stimulatory cycles of 24, 48, or 72 h with a main light period of 6 h during each cycle and interrupting the ensuing long dark periods with 1-h photoperiods.

Male house finches collected in August and early September, 1963, caged, and maintained as previously reported[2], were subjected to at least two months of daily cycles of 6 h of light and 18 h of darkness before experimentation. Ambient temperatures varied from 20° to 28° C. Birds were not in sound-proof chambers. Three experiments were conducted (Fig. 1). Exp. *A* began on November 22, 1963, and lasted 20 days. Control birds received repeated cycles of 6 h of light and 18 h of darkness, whereas the experimental birds received cycles of 6 h of light and 18 h of darkness plus an additional hour of light 12 h after the onset of the main 6-h photoperiod. Exp. *B* began on November 21, 1963, and lasted for 22 days. Control birds received repeated cycles of 6 h of light and

42 h of darkness, comprising a basic 48-h cycle. The different groups of experimental birds received an additional hour of light 12, 24, or 36 h after the onset of the main 6-h photoperiod. Exp. *C* began on January 3, 1964, and continued for 54 days. Control birds received 6 h of light and 66 h of darkness in repeated 72-h cycles. The experimental groups received an additional hour of light 24, 36, or 48 h after the onset of the main 6-h photoperiod. At the termination of each of the above experiments the birds were unilaterally castrated, and released. Other procedural details are the same as has been reported elsewhere[2].

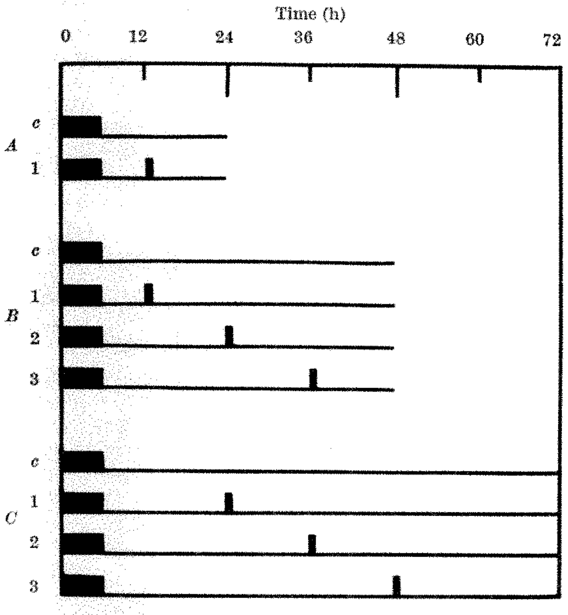

Fig. 1. Scheme of 3 experiments, *A*, *B* and *C*. The vertical bar represents the light period, while the horizontal line represents the dark period in each cycle. One hour of light was given during the dark periods at the time indicated

Exp. *A* is a typical interrupted-night experiment (Table 1). The control birds (maintained on a short-day cycle) did not show testicular enlargement. However, when one additional hour of light was given during the middle of the 18-h dark period the experimental birds behaved as if they had been exposed to long days even though the total amount of light (7 h) was substantially shorter than their critical day length (10–12 h; W. M. Hamner, unpublished results). This response is typical of many photoperiodically sensitive organisms in that the long-day response is obtained when the long dark period of an otherwise short day is interrupted with a brief exposure to light. Such a response does not require the introduction of the circadian rhythm hypothesis for its explanation, although the results are compatible with such an explanation. An alternative hypothesis, equally valid on the basis of these data, involves the postulation that the 1-h photoperiod interacts with the preceding 6-h light period which began the cycle[1].

In Exp. *B* the control birds received no additional light during the 42-h dark period of the repeated 48-h cycle and, consequently, testicular maturation did not occur. In the experimental groups, those which received a supplementary hour of light at the 12-h point exhibited the rapid testicular recrudescence seen in Exp. *A*. In contrast, light at the 24-h point was not stimulatory. On the basis of the circadian rhythm hypothesis this would be expected since this light, falling 24 h after the onset of the main 6-h photoperiod, was presumably in appropriate relation to the circadian rhythm entrained by the main photoperiod. According to this same argument, light at the 36-h point should be stimulatory, but only one of the 11 birds on this treatment showed testicular maturation (left testis weight, 13·2 mg). Although seemingly insignificant, the testicular enlargement of this single bird might be considered evidence that light at the 36-h point is mildly stimulatory since during those 22 days of treatment the birds actually received only 11 inductive cycles. Even if one assumes that all these 11 birds would have had larger testes with longer treatment, this 48-h cycle experiment would still not be a convincing demonstration of the circadian control hypothesis because, as has been argued for the 24-h cycle, light interactions with the preceding or succeeding main light periods could be adequate signals.

Table 1. WEIGHTS (MG) OF THE LEFT TESTIS OF HOUSE FINCHES FROM THREE EXPERIMENTS, *A*, *B* and *C*

0·2	8·3	0·2	8·0	0·3	13·2				
0·6					2·4				

If light at the 36-h point is indeed weakly stimulatory, then an experimental treatment repeated for more than 22 days should be more effective. Exp. *C*, therefore, was continued for a longer time (54 days) than either Exp. *A* or *B*. The control birds received no supplemental light during the 66-h dark periods of the repeated 72-h cycles, and, with one exception, did not show overt testicular enlargement. Additional light at the 24- and 48-h points was apparently not stimulatory either, because none of the birds on these cycles had enlarged gonads. But when light was given at the 36-h point in the cycle testicular maturation occurred. The stimulation of testicular activity with 1 h of light at the 36-h point in a 72-h cycle, in contrast to the lack of stimulation at the 24- and 48-h points, seems to eliminate the possibility of a simple light interaction with the previous or succeeding main light periods and seems to provide a convincing demonstration of the validity of the circadian rhythm hypothesis.

According to the circadian hypothesis the control birds on the 72-h cycle in Exp. *C* should have shown no testicular maturation. However, one of these birds did respond (left testis weight, 20·3 mg). A possible explanation of this single deviation is inherent in this hypothesis. These rhythms are called circadian because they are not exactly 24 h in periodicity. Let us assume that the rhythm of this particular bird, entrained by the main photoperiod, was running a little faster or a little slower than 24 h during the 66-h dark period. It seems possible that its rhythm might accumulate this daily deviation during the almost 3-day dark period so that the succeeding main light period could actually interact with the recurrent light-sensitive phase of the rhythm to stimulate testicular maturation.

I thank G. A. Bartholomew, K. C. Hamner, and R. A. Boolootian for their advice. This work was supported by U.S. National Science Foundation *G*-23983 (to K. C. Life-cycle of *Ectocarpus siliculosus* from Naples, Italy

During an attempt to grow sexual plants of *Ectocarpus siliculosus* in laboratory cultures, some observations were made which are not consistent with the present-day view of the life-cycle of this species.

Ectocarpus siliculosus was obtained from Naples in 1959. No unilocular sporangia were present on these plants. Swarmers from the plurilocular sporangia were isolated and developed to plants showing a distinctly different morphology: they had a well-developed basal system of rhizoids from which rises a great number of erect unbranched filaments up to 15 mm long (Fig. 1). When cultivated at 20° C these plants form plurilocular sporangia only, and their spores again give rise to the same plants. This cycle can be repeated indefinitely. When grown in 13° C, however, unilocular sporangia are formed[1,2]. One unilocular sporangium was isolated. The swarmers did not leave the sporangium but germinated inside, the germlings rupturing the sporangium wall in a later stage. From this accumulation of germlings eight filaments, each about 10 cells long, were cut off and isolated. These fragments regenerated to adult plants. Four of the regenerates were of the small, unbranched type, and cultivation at 13° C induces them to form unilocular sporangia. The other four regenerates were plants growing up to 20 cm long, with no noticeable basal system and typical pseudodichotomous branching (Fig. 2). These plants closely resemble the material originally obtained from Naples. Cultivation at 13° C does not induce the formation of unilocular sporangia on these plants. Plurilocular sporangia are readily formed, and the swarmers of these sporangia develop to plants of the small, unbranched type, which are again able to form unilocular sporangia at 13° C.

Three workers[3-5] have been concerned with the cytology of *Ectocarpus siliculosus*. They agree that the first nuclear division during the formation of the unilocular sporangium is the meiosis, and therefore the plants on which unilocular sporangia occur are diploid. At Woods Hole[5] and Naples[4] the swarmers leaving the unilocular sporangium are considered to be neutral and to give rise to the sexual generation. At the English coast[3] and at Rovigno, Yugoslavia[4], they are believed to act as gametes, the zygotes developing to new diploid plants. Where there is an alternation of generations in *Ectocarpus siliculosus* the two generations are believed to be identical in their morphological appearance[6]. At Naples, however, only the sexual plants are well known[7].

There are only two reports on *Ectocarpus siliculosus* with unilocular sporangia at Naples. Berthold[8] derived small plants with unilocular sporangia from zygotes. Schussnig and Kothbauer[4] found unilocular sporangia on plants which were only a few mm high. Thus it does not seem surprising that *Ectocarpus siliculosus* from Naples is able to perform two morphologically different phases in culture. As the large, branched plants were derived from a unilocular sporangium and as they closely resemble the well-known gametophytes at Naples[7], it seems likely that they represent the haploid gametophytic phase. To certify this, a large number of combinations of the swarmers from the plurilocular sporangia of these plants were made, but no sexual fusion has been observed so far. There was only one occasion when a combination of swarmers from all four clones resulted in about 1 per cent cells having two plastids and two eyespots. This might be taken as indirect evidence that the large branched plants are really gametophytes and their swarmers potential gametes. However, these swarmers readily germinate without any detectable fusion and develop exclusively as plants of the unbranched type, forming unilocular sporangia at 13° C. It would be interesting to know the cytological processes which accompany these events. The observations reported here suggest that the life-cycle of *Ectocarpus siliculosus* at Naples is considerably more complicated than was believed until now.

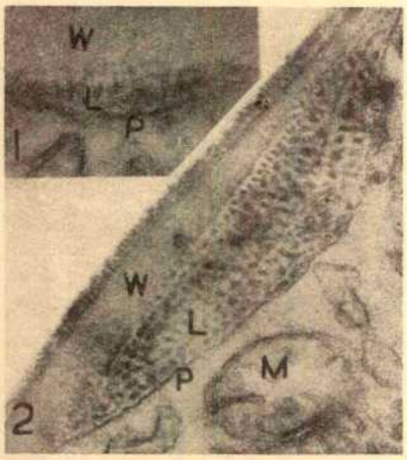
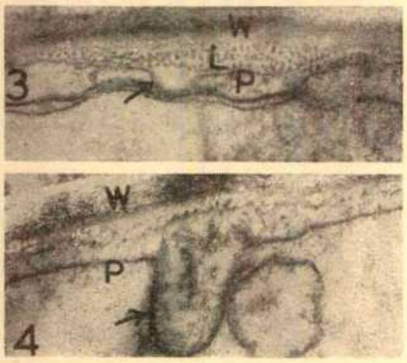
Occurrence of Lomasomes in Mesophyll Cells of 'Khapli' Wheat

Moore and McAlear coined the name 'lomasome' (λωμα—border; σωμα—body) to describe the sponge-like structures which they observed between the cell walls and plasmalemmas in the hyphæ of several species of fungi under the electron microscope. They considered that lomasomes were characteristic of, and peculiar to, the fungi and suggested that they might be of potential value in determining the phylogenetic origin of the Eumycota. This appears to be unlikely since we have found apparently identical structures in the mesophyll cells of wheat, *Triticum dicoccum* var. 'Khapli'.

Healthy primary leaves about 15 days old and free of any fungal infection were cut into small pieces, fixed in 2 per cent unbuffered potassium permanganate for 4 h at 0° C, dehydrated in an alcohol series and in propylene oxide and embedded in 'Epon'. Sections were cut, using a diamond knife, stained with lead acetate and examined in a Philips 100*B* electron microscope. Granular bodies between the cell walls and the plasma membranes of mesophyll cells were identified as lomasomes (Figs. 1 and 2). They appeared to originate from the fusion of intracellular vesicles with the plasmalemma and the formation of an opening resulting in a discharge of the contents of the vesicles from the protoplast, as suggested by Moore and McAlear[1]. Evidence of such a process was observed repeatedly and is illustrated in Figs. 3 and 4.



Figs. 1 and 2. Lomasomes (*L*) in mesophyll cells of 'Khapli' wheat. *M*, mitochondria; *P*, plasma membrane; *W*, cell wall (× *c*. 42,700 and 30,700 respectively)



Figs. 3 and 4. Fusion of vesicles (arrows) with plasma membranes and discharge of contents. (× *c*. 19,000 and 27,300 respectively)

We believe that these observations are the first to record the occurrence of lomasomes in a higher plant. It is noteworthy that so far we have not found either secretory vesicles or lomasomes in the mesophyll cells of another species of wheat, *Triticum compactum* var. 'Little Club'. This is surprising but suggests that their occurrence in this species is at least infrequent. 'Khapli' wheat is resistant, whereas 'Little Club' is susceptible to most of the known races of stem rust of wheat. Whether or not the rapidity and efficiency with which foreign substances can be excreted from mesophyll cells via vesicles have any connexion with rust resistance is not known, but the possibility is an intriguing one.

ENTOMOLOGY

Guanine in the Excreta of the Boll Weevil

The common purine found in insect excreta is uric acid. Reports of other purines in Coleoptera are rare. Xanthine and hypoxanthine have been reported in Lepidoptera[1,2] and hypoxanthine in Diptera[3]. Ordinarily guanine would be expected to deaminate oxidatively to xanthine and undergo further oxidation to uric acid. Although we have found uric acid to be the principal nitrogenous excretory product (24 per cent of fæcal nitrogen) in the boll weevil, *Anthonomus grandis* Boheman, we have also located and identified the compound guanine.

Fæces were collected from adult weevils fed on a modification of Vanderzant's diet[4]. These were pooled, the lipids removed by washing three times with chloroform : methanol (2 : 1), then extracted with 0·5 N perchloric acid at 0°, neutralized with potassium hydroxide, and filtered. Aliquots of the extract were chromatographed singly and two-dimensionally on Whatman No. 1 filter paper. The systems used were aqueous 65 per cent (v/v) isopropanol 2 N with respect to hydrochloric acid[5], water *p*H 10 (Levenbook, ref. 6), and the upper phase of a mixture of *sec*-butanol and water[7]. Spots were located by ultra-violet light, and tentative identification was made by comparison with standard compounds in each system.

Spots were eluted with 0·1 N hydrochloric acid and again with phosphate buffer, *p*H 12·7, and their spectra determined by a Beckman *DK2A* spectrophotometer. Corroborative identifications were made from maxima,

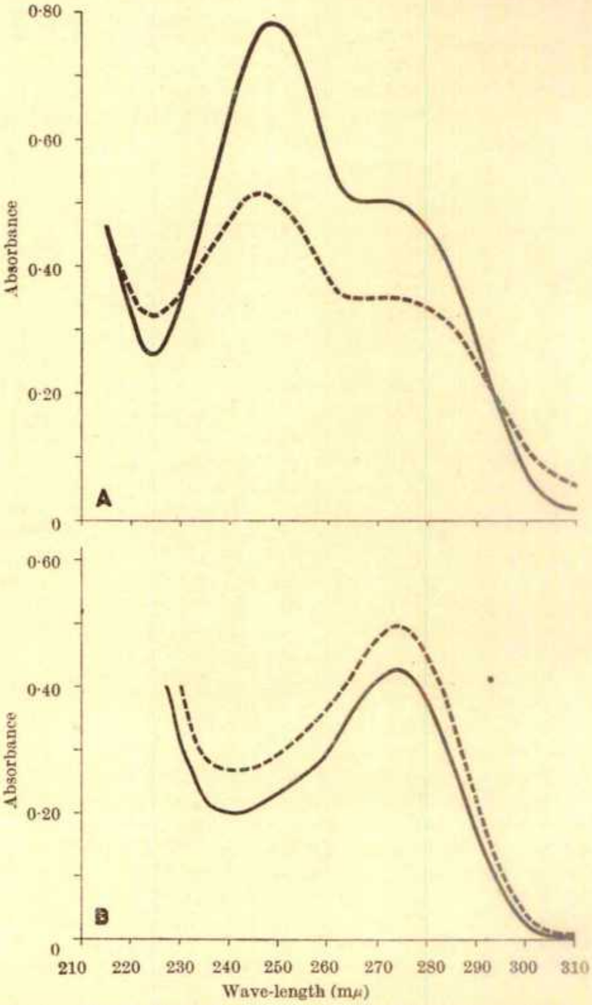

Fig. 1. Ultra-violet spectra of guanine derived from boll weevil fæces and a guanine standard. Solvents: *A*, 0·1 N hydrochloric acid; *B*, phosphate buffer, *p*H 12·7. ——, Standard; - - - -, extract

minima, and ratios of E 250/E 260 and E 280/E 260 at pH 1 and 12·7. These spectra, along with those of an authentic compound, are shown in Fig. 1.

Quantitative determination of the eluates at pH 1 was made spectrophotometrically by using differential extinction values[8]. Guanine accounted for about 3 per cent of the fæces nitrogen. This is an approximate value, since complete chromatographic separation was not achieved with any of the systems used.

In a determination of whether guanine might be excreted by other curculionids, the fæces of the plum curculio, *Conotrachelus nenuphar* (Herbst), fed on apples, were examined in exactly the same manner described here. No guanine, but xanthine, was found. Hence the finding of guanine in the boll weevil appeared to be unique and probably could not be ascribed to an artefact of the extraction procedure.

Accumulation of hypoxanthine in the excreta of *Drosophila melanogaster* Meigen has been ascribed to a deficiency of the enzyme xanthine dehydrogenase (oxidase)[9]. One could speculate that appearance of guanine might be the result of a deficiency of the enzyme guanase.

GENETICS

Ethylation versus Methylation in Mutation of *Escherichia coli* and *Drosophila*

THE monofunctional ethylation reaction has been established as an inducer of genetic mutation in a number of test organisms. In particular, ethylation appeared to be unique among the alkylation reactions in its ability to induce mutation in the first lytic cycle following treatment of extracellular phage, since methylation, propylation, and other analogous reactions were not effective[1]. More recently, however, it was reported[2] that the methylation and propylation reactions do produce slight increases in mutation on extracellular phage, but at considerably lower frequencies than the ethylation reaction. Although such a distinct competence of the ethylation reaction does not appear to be preserved in bacteria and higher organisms, ethylation is nevertheless regarded as a more efficient inducer of mutation than other alkylation reactions.

The present communication reports on experiments designed to compare the relative mutagenic effectiveness of the ethylation and methylation reactions on the bacterium, *Escherichia coli*, and a multicellular organism, *Drosophila melanogaster*. On both test organisms, the ability of both alkyl groups to produce forward mutation (from wild-type to mutant) has been studied, since back-mutation (from mutant to wild-type) may involve molecular changes only capable of reversion by one of the reactions. The ethyl group was introduced via diethyl sulphate, the methyl group via dimethyl sulphate; both reagents were supplied by British Drug Houses Ltd. (B.D.H.) and contained 1·117–1·180 g/ml. and 1·32–1·33 g/ml., respectively.

(1) *Escherichia coli*. The ethylation reaction has been described as a potent inducer of genetic mutation in bacteria[3] under conditions where virtually all the cells survive the treatment, and the methylation reaction has been shown[4] to induce the reversion of certain bacterial mutants.

Comparison of the mutagenic effectiveness of the ethylation and methylation reactions on *E. coli* reported here is consequent on the treatment of logarithmically-growing cells of *E. coli* with dimethyl sulphate or diethyl sulphate, and scoring mutation from phage-sensitivity to phage-resistance.

E. coli B was grown in broth from an overnight culture to about 2×10^8 cells/ml. and resuspended for treatment in *M*9-buffer at about 8×10^8 cells/ml. Since neither diethyl sulphate nor dimethyl sulphate is miscible with water, dilution of the reagent was into 80 per cent ethyl alcohol before addition to the culture. At the concentration used for treatment (1×10^{-3} M), this involved diluting the reagents 100 times (0·1 ml.–9·9 ml.) and adding either 0·13 ml. (diethyl sulphate) or 0·095 ml. (dimethyl sulphate) to 10 ml. of the cell suspension; the control culture was identically handled and 0·13 ml. of the diluent was added. Treatment of the cells was for 15 min at 37° C, giving 100 per cent survival in the control and diethyl sulphate cultures, and 2 per cent survival in the dimethyl sulphate culture.

After treatment, the cells were diluted tenfold, washed, resuspended in broth at about 1×10^8 viable cells/ml., and aerated at 37° C. Samples were withdrawn immediately (zero time), and after various times of aeration, for viability counts and for scoring mutant phage *T*4-resistant (*B*/4) cells. Mutants were assayed by adding *T*4 phage at a multiplicity of between 50 and 100 for 5 min to a cell sample, spreading appropriate aliquots on to broth plates pre-spread with about 10^{10} phage particles, and incubating for at least 24 h at 37° C. Logarithmic growth of cells was preserved throughout the experiments by diluting the culture 20 times at zero time and after each two-hour period of aeration.

Mutation to phage-resistance is not expressed immediately on the cell (zero-point mutation), but only after several generations of growth. Usually at least six divisions of the cell are required for the complete phenotypic expression of phage-resistant cells (end-point mutation).

Table 1 illustrates the results of a typical experiment when the control, the diethyl sulphate-treated cells, and the dimethyl sulphate-treated cells are allowed to grow in broth over a period of 8 h; samples are taken at zero time and after each 2-h period of growth. While there is no indication of an increase in zero-point mutation (*B*/4 cells per 10^7 cells before treatment was 25), the end-point mutation is significantly higher after treatment with dimethyl sulphate compared with the control and treatment with diethyl sulphate. Since the expression of end-point mutation appears complete and constant after about 6 generations of growth, the mutation fre-

No. of lethal chromosomes	2	96	22
Percentage of sex-linked recessive lethal mutations	0·25	11·85	2·11

quencies ($B/4$ cells per 10^7 cells), averaged over the 4-, 6-, and 8-h periods of aeration, are control (24), diethyl sulphate (39), and dimethyl sulphate (90) ; both alkylating agents stimulate the rate of division of the cells compared with the control cells. The increase in the frequency of $B/4$ cells by dimethyl sulphate does not appear to be due to selection as a consequence of the higher kill, since a spontaneous and a 'dimethyl sulphate-induced $B/4$ mutant' were equally sensitive to treatment with dimethyl sulphate as the experimental culture.

Although a mutagenic effect of diethyl sulphate on *E. coli* at this concentration (1×10^{-3} M) may be questioned, its low toxic effect enables much higher doses to be tested. For example, the concentration of diethyl sulphate can be increased 100 times (to 0·1 M), giving 20 per cent survival of cells, and an end-point phage-resistant mutation frequency of about 500 $B/4$ cells per 10^7 cells ; there is no increase in zero-point mutation under these conditions.

At the test concentration (1×10^{-3} M), however, the methylation reaction produces a higher mutagenic effect than the ethylation reaction. The higher toxicity of the methylating compound does not permit much higher doses to be tested ; increase in the dimethyl sulphate concentration (to $1·5 \times 10^{-3}$ M) to give a greater kill (99·9 per cent) does not increase the mutation frequency much above 100 $B/4$ cells per 10^7 cells.

(2) *Drosophila melanogaster*. Previous work has shown that in *Drosophila melanogaster* both diethyl sulphate and dimethyl sulphate are mutagenic by a larval feeding method[5,7], and diethyl sulphate is mutagenic by an adult feeding method[6,7]. Work reported here on the relative mutagenic effectiveness of the methylation and ethylation reaction on *Drosophila* has been carried out using the adult feeding method.

The method is as follows : Several one-pint milk bottles, the bottoms of which were covered with a double thickness of filter paper, had the filter paper saturated with a solution containing 2 parts of distilled water to 1 part of absolute alcohol, 5 per cent glucose, and either diethyl sulphate or dimethyl sulphate to give a concentration of $3·8 \times 10^{-4}$ M. Since neither alkylating agent is miscible with water, alcohol was present in the treatment solution to disperse the globules otherwise formed. The filter paper was kept saturated during the period of treatment by adding 3 drops of the treatment solution 4 times daily.

Fifty newly-emerged wild-type 'Oregon-K' adult males were starved for 24 h, and placed for 24 h in one of the treatment bottles ; the treatment solution was the sole supply of nourishment during this time. After treatment, the males were examined for sex-linked recessive lethal mutations by the Muller-5 (*Basc*) method, using a brooding pattern where each treated male was individually mated to 2 females for 3 days.

The first brood samples recorded in Table 2 represent the mutational responses to adult feeding of diethyl sulphate and dimethyl sulphate on germ cells which were predominantly present as mature spermatozoa at the time of treatment. Diethyl sulphate is seen to be 5–6 times more effective than dimethyl sulphate in inducing sex-linked recessive lethal mutations on mature *Drosophila* spermatozoa at similar levels of survival of the treated flies.

I thank Prof. J. M. Thoday for supplying laboratory facilities, and the British Empire Cancer Campaign for Research for financial support.

Activities of Pseudocholinesterases (Acylcholine-Acylhydrolase, EC 3.1.1.8) in *Macaca mulatta* (*rhesus*) and *Cercopithecus aethiops*

LEHMANN *et al.*[1,2] and Kalow *et al.*[3,4] first pointed out that the existence of some different pseudocholinesterase-variants in human serum is based on a genetical polymorphism. These investigations had been induced by the observation that some patients show an abnormally prolonged period of apnœa after injection of the muscle-relaxant succinyldicholine. In order to co-ordinate the results and hypotheses which have been published in recent years a 4-allele-model has recently been discussed[5-10]. Liddell *et al.*[11] demonstrated the presence of the same pseudocholinesterase variants which can be found in the sera of normal homozygous, heterozygous and atypical homozygous individuals, also in liver, kidney, brain, ileum and skin of man. Tashian and Shaw[12] were the first to show the heredity character of variants of human acetylcholinesterases. The same has been shown for various esterases of other species[13-16]. Cholinesterases with a different affinity from a number of cholinesters could be detected in the plasma of nearly all animals examined[17-21]. Except for human sera, those of other primates have not been tested to any extent. In our own experiments, and in contrast to the results of Kalow[22], the pseudocholinesterases of *Macaca mulatta* (*rhesus*) have quite different values from that of normal human serum in case of inhibition with dibucaine.

Examining the sera of *Macaca mulatta* (*rhesus*) and *Cercopithecus aethiops*, we obtained the following results: the protein-levels in the sera of *Macaca* and *Cercopithecus* were somewhat higher in comparison with human serum. The activity was measured with benzoylcholine as substrate in the optical test as described by Kalow[3]. The values of activity (and the specific activities) of *Macaca* have been found to be of the same order as that of man, while the sera of *Cercopithecus* show no or, at the most, very small activities. Table 1 shows the estimated activities, specific activities and protein values of 41 sera from *Macaca* and 14 sera from *Cercopithecus*. The enzyme proteins of pseudocholinesterase, which show nearly the same values of activity in the sera of *Homo* and *Macaca*, seem to be very different in protein structure: as demonstrated in Table 2 the inhibitor constants differ essentially (using dibucaine and sodium fluoride as inhibitors). In the case of human normal homozygotes (about 96 per cent of the population) an accumulation of DN about 80 and FN about 61 has been found[3,4,9,23-25]. In contrast

Table 2. INHIBITOR CONSTANTS (DIBUCAINE NUMBERS AND FLUORIDE NUMBERS) OF PSEUDOCHOLINESTERASES FROM *Macaca mulatta* COMPARED WITH THE VALUES IN MAN

	Macaca mulatta	*Homo*		
		Normal homozygote	Heterozygote	Atypical homozygote
Dibucaine No.	$\bar{x}$ = 98·4 s = 3·1 $s\bar{x}$ = 0·5	71–85	43–70	≤20
Fluoride No.	$\bar{x}$ = 3·0 s = 2·8 $s\bar{x}$ = 0·4	≥55	40–55	20–27
n	41·0	See refs. 3, 4, 9, 24, 25, 26		

to these values, dibucaine inhibits the transformation of benzoylcholine by serum of *Macaca* at equal concentrations at the rate of 97–100 per cent; sodium fluoride exerts only a very small inhibiting effect on the pseudocholinesterase of *Macaca*. In the agar-diffusion test[26] also (α-naphthylbutyrate as substrate), there are great differences in the behaviour of human serum and that of *Macaca* and *Cercopithecus*, on the other hand[27]. In view of the foregoing results, it cannot be decided whether there is a polymorphism of pseudocholinesterases in *Macaca* and *Cercopithecus*. Further investigations (probably using other substrates and more suitable inhibitors) may clarify this problem.

VIROLOGY

Hæmagglutination Reaction with Vaccinia Virus: Agglutinability of Red Cells from Turkeys

Some authors[1–3] have reported that saline preparations of vaccinia virus, when mixed with suitable suspensions of red cells from certain adult fowls, caused hæmagglutination, which could be inhibited by antiserum to vaccinia. Only 50 per cent of the fowls were found to have cells agglutinable with vaccinia virus and the phenomenon appeared to operate independently of breed, sex or age.

Later work[4,5] indicated that red cells from birds of the Leghorn breed showed a higher incidence of agglutinability than did cells from other breeds.

Recent work[6] has confirmed the results of Clark and Nagler[2] in respect of both fowl and mammalian cells. An interesting finding of the work has been the observation that red cells from all turkeys were agglutinated by vaccinia virus.

Red cells (0·5 per cent saline suspension) from 108 'Broad Breasted Bronze' and 106 'Beltsville' turkeys were tested by titrating vaccinia antigen prepared from lymph from infected rabbits; cells from known positive and negative fowls served as controls. The tests were carried out in tubes using the technique of McCarthy[4]. All the turkeys except one had cells which showed complete (+ +) agglutination. This agglutination was proved to be specific, since it could be inhibited by antiserum to vaccinia. The results of the experiments are shown in Fig. 1.

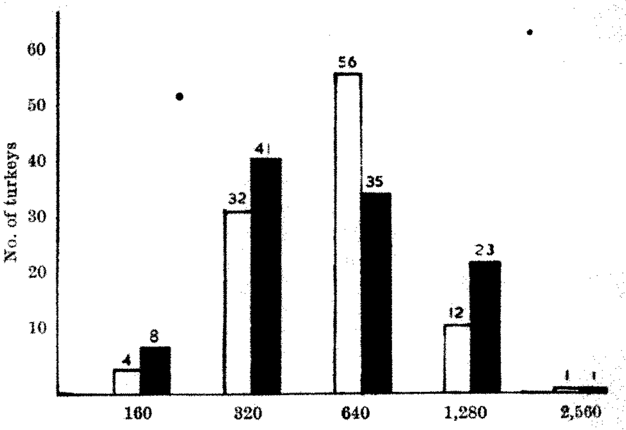

Fig. 1. Hæmagglutination titres (+ +) obtained with vaccinia virus against red cells from bronze (■) and white □ turkeys

SOIL SCIENCE

Electro-osmosis in Frozen Soil

Water can be transported in unfrozen soil under an electrical gradient. This process, which is called electro-osmosis, is due to an excess of positive ions over negative ions in the water near a solid surface. The amount of water which can be transported by electro-osmosis is such that in some instances it has been used to stabilize soft clay embankments. The purpose of our experiment was to measure the extent to which water can be moved through the films of unfrozen water in a frozen soil.

Ice and adsorbed water can be in equilibrium in a soil at temperatures well below freezing. The adsorbed water in a frozen soil has been called unfrozen water. This term is used to indicate that the adsorbed unfrozen water in frozen soils is different from that of ice. For example, in sodium Wyoming bentonite at − 5° C as much as 0·8 g of unfrozen water per g of clay has been reported by Kolaian and Low[1], using a calorimetric method.

This experiment indicated that some water remains unfrozen, but it does not give information about the mobility of water and ions in the film of unfrozen water. Moreover, even if ions and water can migrate in the unfrozen film, the film might not be continuous through the soil matrix. Vershinin *et al.*[2] measured electrical a.c. conductance of frozen ground. Since the conductance of the frozen ground was higher than one would expect for dry soil or ice, their results suggested current flow in continuous films of unfrozen water.

When water freezes to ice most ions are expelled from the ice phase and remain in the water phase. As the salt concentration rises the ions are not incorporated in the ice lattice, but instead form brine pockets in the ice. The same principle applies to the water in soils. On freezing a soil, ice forms in the large pores or, in some instances, ice segregates as lenses. The exchangeable cations surrounding the soil particle are crowded in a film of unfrozen water on the surface. In this unfrozen film the conditions for electro-osmosis are satisfied; there is an excess of cations over anions near a solid surface.

The following describes our experimental method to investigate the occurrence of electro-osmosis in frozen soils. A rectangular slab of soil was frozen between two brass plates in a refrigerated room at −30° C. Freezing a soil rapidly at low temperatures has the advantage in that little water movement occurs during freezing. The frozen slabs of soil were cut to size and placed in 'Lucite' cells (1 cm × 5 cm × 5 cm). Electrodes (1 cm × 5 cm) were frozen to the sides of the sample. A thermistor was used to record the temperature, while an electrical potential gradient of 1 V/cm was applied across the frozen soil.

Table 1. INITIAL AND FINAL WATER CONTENTS (WEIGHT OF WATER PER WEIGHT OF CLAY × 100 PER CENT) AFTER THE FROZEN SAMPLE WAS EXPOSED TO AN ELECTRICAL GRADIENT OF 1 V/CM FOR 24 H

Soil	Temperature (° C)	Initial water content	Final water content Within 1 cm from anode	Within 1 cm from cathode
Wyoming bentonite	−2·0° C	341	275	456
	−1·5° C	265	134	310
New Hampshire silt	−1·5° C	30	27	32
	−1·0° C	28	21	40

Water was transported in the frozen soil towards the cathode. The initial and final water contents (unfrozen water and ice) of two soils after electro-osmosis are presented in Table 1. Initially, the film of unfrozen water is in equilibrium with ice in the sample, but when the unfrozen water is transported from the anode regions, the film of unfrozen water is depleted. It is replenished by the melting of ice in that region. In the final state all ice is removed from the anode region and large bodies of ice are formed in the vicinity of the cathode. Shrinkage cracks form at the anode.

The experimental results show that a considerable amount of unfrozen water can be transported in frozen soil under an electrical gradient. For unfrozen soils the migration of water under electrical and temperature gradients has been related. One expects this also to be valid for frozen soils. The amount and mobility of unfrozen water are such that they can be of practical significance in redistributing moisture under temperature gradients in perennial frozen ground.

Silcretes of Central Australia

THE widespread occurrence in central Australia of silcrete which there caps numerous mesas and forms extensive stony pavements on the dissection slopes below them has long awaited a satisfactory explanation. A recent recording[1] of the nature and disposition of certain lateritic and desertic soils, taken in conjunction with the location of major drainage divides and the pattern of endoreic streams to the Lake Eyre depression[2], throws new light on the problem and indicates the following sequence of pedologic and geomorphic events : (1) A regional development of Lateritic Red Earths occurred across what is now the watershed of eastern and northern Queensland. The lateritic weathering was accompanied by the usual loss of silica in the drainage water, one part going to the Pacific Ocean and the Gulf of Carpentaria and the other to the precursors of the present-day ephemeral and endoreic streams, the Georgina, Diamantina, Barcoo Rivers and Cooper's Creek, the courses of which then extended up to 200 miles further south-west. (2) The silica which moved south-westerly was deposited in a large array of rocks and softer deposits of widely different chronology, including variably weathered sandstones, shales and quartzites, and calcareous, gypseous, saline and alunitic formations. To-day these materials are to be found beneath the silcrete caps of the mesas, and the later group at least indicate aridity and/or restricted drainage at the time of their deposition. (3) The large, gently sloping silcrete surface so formed was disrupted and eroded following the development of the down-warped Lake Eyre basin. This depression and its compensating upwarp to the west and south caused differences in elevation of the order of 1,000 ft. with the lowest point below sea-level. This provided a new, internal, and very low base level for erosion and caused rejuvenation and down-cutting of the streams coming from the north-east and reversal of the drainage in the silcrete area to the west and south of the newly formed depression. The combination of earth movement and erosion caused the break-up of the extensive silicified surface into numerous mesas and associated larger areas of fragmented silcrete represented to-day by the pavement on the Stony Desert Tableland Soils.

There thus appears to be in Australia a continental example of absolute accumulation of silica. The distant edge of the silcrete area is about 900 miles from the original source, that is, the Lateric Red Earth tableland from which the Great Dividing Range has also since been sculptured. So far as is known, this genetic linking of the two now dismembered landscapes with once active processes of release and deposition of silica is on a uniquely large scale.

PSYCHOLOGY

Stereoscopic Shadow-images

THE following simple arrangement makes it possible to project, in stereoscopic depth, three-dimensional objects such as wire models of molecular or crystal structures. Small models may be presented enlarged in three dimensions, magnifications of ten or more times being possible. The optical arrangement consists of nothing but a pair of small bright light sources, separated horizontally by a few inches. The sources are placed behind 'Polaroid filters', set at orientations differing by 90°. The point polarized sources give a pair of shadow images of an object, such as a wire model, placed between them and a silver screen. Alternatively, back-projection with a ground-glass screen can be used; but the screen must not de-polarize the light. When the shadows are viewed through crossed 'Polaroid' glasses, they are fused by the brain to form a single stereoscopic shadow-image lying in space.

There is no problem in explaining this effect. The point sources cast shadows on the screen which are flat projections from slightly different positions. The shadows have the disparity of retinal images for eyes placed at the sources. The observer's brain fuses the two disparate shadows into a single stereoscopic shadow, looking incredibly like a real, but jet black, object. It lies in space either in front of or behind the screen, depending on which eye accepts which shadow. By using polaroids oriented at 45° from horizontal, the stereo shadow-image may be placed before or behind the screen simply by reversing the spectacles.

Suitable light sources are miniature filament, 12-V, 100-W tungsten-iodine lamps. The filaments should be oriented vertically, to give maximum horizontal resolution, which is important for giving maximum information of depth through disparity.

Magnification of the normal x- and y-axes is given simply by the ratio of the distance of the object from the lights to the object from the screen. Magnification in depth (z-axis) can be controlled by the horizontal separation of the lamps. In practice a magnification of at least times 10 may be given; but the apparent size of the three-dimensional shadow-image is generally less than might be expected, because of perceptual size constancy.

When the object appears to be in space before the screen it looks smaller than when behind it, though the physical size is of course identical with either orientation of the polaroids. A further perceptual effect is most marked: when the observer moves his head, the stereo shadow-image appears to move with him, to slide across the screen, and rotate to follow the observer as though continuously aimed at him. This is because there is no motion parallax although the image lies perceptually in three dimensions: this corresponds to a normal object rotating to keep the same aspect to the observer though he moves. So he sees movement though his retinal images remain unchanged. When the observer moves away from the screen, the shadow-object does not shrink or lose its depth as might be expected; the reduced angle of convergence of the eyes evidently re-scales the retinal disparity mechanism, so that a given disparity between the retinal images gives greater visual depth. This is indeed fortunate, for the shadow-image appears very similar over a wide range of distance, and so it can be used with effect in a large lecture hall for demonstrating suitable objects. They may be moved or touched by the demonstrator, which makes this a technique having advantages over photographic stereo projection. It is also a useful tool for investigating perception of depth while the observer is moving, and can form the basis of simulators for experiments on the guiding of aircraft and space vehicles.

This technique was devised for experiments supported by U.S. Air Force grant *AF-EOAR* 63–93, monitored by the European Office, Office of Aerospace Research.

Retroactive Interference in Short-term Memory

In investigating short-term memory (a term generally used to cover the period of from one to sixty seconds) an important question is whether or not retention is influenced by factors known to be important in long-term memory. One such factor is retroactive interference. Broadbent[1] has asserted that retention depends on the duration of the delay rather than the nature of any activity during the delay. But he rests his case on evidence that retention is impaired by increasing the delay while keeping the activity as constant as possible. Direct evidence that variation of the intervening activity is ineffective has been lacking, but Baddeley and Dale[2] have shown that in minimal paired-associate learning[3] meaningful similarity fails to affect performance significantly, and this supports Broadbent's contention.

Recently Wickelgren[4] has produced evidence suggesting that acoustic similarity does affect retroactive interference in short-term memory. His technique was to present rapidly (2/sec rate) four letters which had to be remembered, then eight which were to be copied down. Immediately the eight had been copied the subjects had to write out the first four from memory. The crucial variable was the similarity of the eight letters which had to be copied to the four which were being remembered. The letters used were taken from two groups *F L M H S X* and *B C D G P T V* (*Z*). Conrad[5] has shown that within each group acoustic confusions are common, whereas between the groups they are rare. (*Z* does not confuse with *B C*, etc., in English; but with its American pronunciation it is obviously similar to the others and Wickelgren added it.) Wickelgren's results indicate that when the letters to be copied came from the same group as those being remembered, memory was poorer than when they came from the other group. They are not clear-cut, however, since he had to introduce repetition. To illustrate this: if *B C D G* were to be remembered and similar letters had to be copied, the only four letters available were *P T V Z*, so subjects were required to write each twice. With the '*F*' sub-group the problem was even more acute since there were only two spare letters.

The experiment reported here was carried out in order to confirm Wickelgren's findings. To avoid the problems already outlined here the subjects were given three letters to remember and six to copy down. The six always consisted of three different letters each repeated once. For this experiment the '*B*' group was pruned to *B C D G P V*. Forty trials were run, 10 with '*F*' letters to be remembered and '*F*' letters copied; 10 with '*F*' letters to be remembered and '*B*' letters copied; 10 with '*B*' letters to be remembered and '*F*' letters copied; and 10 with '*B*' to be remembered and '*B*' copied. Two series of trials were used. The first was prepared by randomizing the order of the 40 trials. The second was derived from the first by keeping the messages to be remembered constant and altering the messages to be copied, so changing *F–F* to *F–B*, *F–B* to *F–F* and so on. Any influence of order of presentation was in this way controlled. All items were read out by the experimenter in time with a metronome beating at a 2/sec rate. A pause of one beat separated the memory message from the copy message. Ten seconds separated the end of one copy message from the beginning of the next memory message. Subjects were tested in two groups of 17. They wrote out all messages on a specially prepared form. An invigilator checked that they put down the copy message before the memory one.

Performance was scored by counting the number of letters in each memory message which were correctly recalled in both substance and position. The results showed a mean score of 59·4 per cent when the copied message came from a different group of letters to the memory message but only 38·7 per cent when the copied message came from the same group. The individual records of 31 of the 34 showed this effect; its statistical significance is, therefore, extremely high ($P < 0{\cdot}001$). Thus Wickelgren's observation is confirmed and we must conclude that the principle of retroactive interference does apply to short-term memory. The form of the similarity which affects performance, however, would seem to differ from that which influences interference in long-term memory. Meaningful similarity is unimportant over these short periods, but similar-sounding items cause interference. Presumably the basis of coding for normal verbal learning with repeated presentations and with opportunity for rehearsal differs from that used for short-term storage following a single presentation.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Tuesday, September 29

Linnean Society of London, Palæobotany Group (at Burlington House, Piccadilly, London, W.1), at 3.15 p.m.—Scientific Papers.

University of London (in the Wright-Fleming Institute Theatre, St. Mary's Hospital Medical School, Paddington, London, W.2), at 5 p.m.—Prof. R. D. Wright (University of Melbourne): "Actions and Interactions of Aldosterone".*

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "What Data do Designers Need in the Applied Mechanics Field ?"

Society of Chemical Industry, Oils and Fats Group (at the Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 6 p.m.—Prof. W. O. Lundberg: "Some Recent Developments in Fat Nutrition".

Tuesday, September 29—Wednesday, September 30

Cement and Concrete Association (at the Royal Institute of British Architects, London, W.1)—Symposium on "Lightweight Concrete in Building".

Tuesday, September 29—Thursday, October 1

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2)—Conference on "Lasers and Their Applications".

Wednesday, September 30

Institution of Electronic and Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. J. R. Blakey: "Near Field Measurements and the Determination of Aerial Patterns".

Television Society (joint meeting with the British Kinematograph Society, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 7 p.m.—Mr. G. H. Askew, Mr. D. Boston, Mr. P. Lowry and Mr. T. C. Nuttall: "A New 16 mm. Flying Spot Colour Telecine Machine".

Thursday, October 1

Royal Society of Medicine, United Services Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Surgeon Cdr. A. F. Davidson: "Studies of the Principles of Flotation by Life Jackets"; Surgeon Cdr. D. C. McNutt: "Protection from Cold in Air and Water".

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Use of Chains in Handling Machinery".

Television Society (in the Conference Suite, I.T.A., 70 Brompton Road, London, S.W.3), at 7 p.m.—Mr. D. J. Basinger: "Microphones and Sound Effects for Television".

Royal Society of Medicine, Neurology Section (at 1 Wimpole Street, London, W.1), at 8 p.m.—Prof. J. N. Cumings: "Some Lipid Diseases of the Brain" (Presidential Address).

Thursday, October 1—Friday, October 2

Eugenics Society (in the Botany Lecture Theatre, University College, Gower Street, London, W.C.1), at 10.30 a.m. daily—Symposium on "Biological Aspects of Social Problems".

Friday, October 2

The Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research (in the Institute of Physiology, The University, Glasgow), at 5 p.m.—Dr. Donald M. Watkin: "The Impact of Nutrition on the Biochemistry of Ageing in Man" (8th (Annual) Ciba Foundation Lecture).*

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Should Basic Craft Training be done at a Technical College or at a Works ?"

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. R. S. Cahn: "The Future of Chemical Publications".

Saturday, October 3

Nutrition Society (at the London Hospital, Whitechapel, London, E.1), at 10.30 a.m.—Symposium on "Availability of Minerals in Foods of Plant Origin".

Monday, October 5

Institution of Electronic and Radio Engineers, Joint I.E.R.E.-I.E.E. Medical Electronics Group (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Discussion on "Transistorized Biological Amplifiers".

British Society for the Philosophy of Science (at University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. R. Harre: "The Limits of Formalization".

Society of Chemical Industry, London Section (at Shell Centre Theatre, Shell Centre, London, S.E.1), at 6.30 p.m.—Scientific Film Evening.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Students (2) (with a good honours degree) **in the Department of Physiology and Pharmacology**—Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (October 1).

Assistant (preferably with experience in a medical or scientific library or publishing) for the *British Medical Bulletin*, for duties which will include detailed checking and preparation of material for publication in the bulletin—The Recruitment Division, The British Council, 65 Davies Street, London, W.1 (October 2).

Assistant Lecturer or **Lecturer in Textiles and Clothing in the Department of Domestic Science**, University College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 8).

Assistant Lecturer in the Chemistry Department—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.C.1 (October 9).

Assistant (with an interest in applied mechanics and/or materials science, a good honours degree in engineering or in an appropriate pure or applied science, and postgraduate experience) **in Mechanical Engineering**—The Secretary of University Court, The University, Glasgow (October 10).

Lecturer or **Assistant Lecturer** (preferably with an interest in petrology) **in Geology**, at Queen's College, Dundee—The Secretary, University of St. Andrews, Queen's College, Dundee (October 10).

Chair of Mechanical Engineering in the Faculty of Engineering, University of Malaya, Kuala Lumpur—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Malaya and London, October 15).

Lecturer in Geology and Pedology—The Secretary, Wye College (University of London), Near Ashford, Kent (October 17).

Chair of Anatomy—The Registrar, The University, Leeds, 2 (October 19).

Lecturer in the Department of Mechanical Engineering, University of Cape Town—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (London and Cape Town, October 19).

Reader in Agricultural Biology at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 19).

Chair of Applied Mathematics at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 22).

Associate Professor of Physiology at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 23).

Lecturer or **Assistant Lecturer** (with a degree in electrical engineering, and an interest or postgraduate experience in the field of electronics, preferably microwaves or semi-conductors) **in the Department of Electrical Engineering**, University of Melbourne, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (October 24).

Professor of Organic Chemistry—The Registrar (Room 22, O.R.B.), The University, Reading (October 24).

Lecturer/Senior Lecturer in Agricultural Entomology at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 26).

Chair of Pathology at the University of Tasmania, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 30).

Lecturer in Physics; and a **Senior Lecturer in Physics** at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 30).

Lecturer (with a university degree in chemical engineering, plus five years' approved industrial experience) **in Chemical Engineering**—The Director, The Swinburne Technical College, John Street, Hawthorn, E.2, Victoria, Australia (October 31).

Chair of Horticulture at Lincoln College, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 14).

Post-doctoral Fellows (2) (physical chemists or physicists) to carry out research on atomic reactions—The Registrar, University of Canterbury, Private Bag, Christchurch, New Zealand (November 30).

Plant Pathologist (national of the United Kingdom or the Republic of Ireland, with an honours degree in natural science or agricultural botany and at least two years' experience in plant pathology) in Tanganyika, for duties at the Coffee Research Station, largely in connexion with the breeding programme for rust resistance—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/173/08.

Post-doctoral Research Fellow in Protein Physical Chemistry—Dr. C. M. Kay, Department of Biochemistry, University of Alberta, Edmonton, Canada.

Research Student (with a first- or second-class honours degree of a British university in physics or metallurgy) **in the Metal Physics Group**, for work on the slip and twinning modes of solid mercury, and will be expected to register for a Ph.D. degree of the University of London—Head of the Physics Department, Battersea College of Technology, Battersea Park Road, London, S.W.11.

Research Chemist (with a good honours degree and several years' research experience, and preferably postgraduate qualifications), to take charge of a laboratory investigating the physical and chemical properties of egg in relation to baking quality—The Secretary, British Baking Industries Research Association, Chorleywood, Rickmansworth, Herts.

Research Student (chemist, physicist or chemical engineer) **in the Department of Chemical Engineering**, for work leading to a higher degree, on the oxidation of free radicals in combustion reactions using a specially designed mass spectrometer—The Secretary, University College, Gower Street, London, W.C.1.

Research Students in Organic and Organometallic Chemistry—The Professor of Chemistry, University of Sussex, Brighton, Sussex.

Senior Pharmacist—The Secretary, Royal Eye Hospital, St. George's Circus, London, S.E.1.

Senior Technician for duties which will include lecture demonstrations and the organization of laboratory classes for students (previous experience in such work essential)—The Secretary, The Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

Silvicultural Ecologist (national of the United Kingdom or the Republic of Ireland, with a degree in forestry, at least ten years' field experience and a thorough knowledge of silviculture in tropical evergreen rain forest, preferably in South East Asia), in Malaya, to plan a system of silvicultural management for Hill Dipterocarp forests—The Appointments Officer, Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 324/105/01.

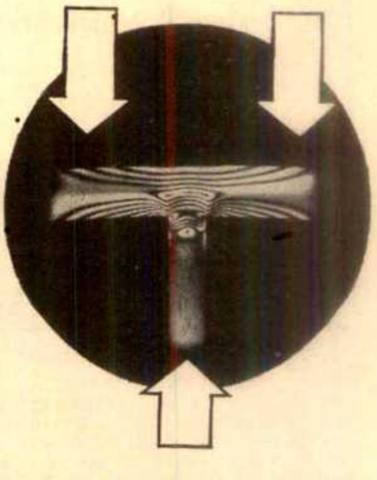
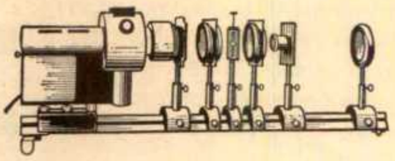
OBSERVING THE EFFECTS OF

← STRESS →

IMPORTANT APPLICATIONS OF SPINDLER & HOYER OPTICAL BENCHES:





Beam of light from carbon arc lamp is gathered in optical condensers, transmitted through polarizing screen, specimen, analysing screen and objective, which projects it on viewing screen. Spindler & Hoyer optical benches feature an automatic feeding device to move carbons uniformly through the lamp and eliminate adjustment. A wide range of sliding carriages and other accessories makes them extremely versatile.

(3) PLASTICS AND GLASS

Mixes are tested on a Spindler & Hoyer optical bench before being passed for manufacture. A test rod is fitted to the bench and subjected to stress. An image showing the effects is then projected for observation, and may be filmed or photographed. In this way the properties of a mix can be controlled and quality maintained. Designs for manufacture are similarly tested, using a model of the section subject to most strain.

Spindler & Hoyer optical benches (used by leading laboratories) have many other time- and money-saving applications, particularly at the design stage in engineering. They are invaluable for demonstrating the principles of mechanics to students. For full details, please contact the sole U.K. distributors,

GREY OF NORWICH

Specialist in Laboratory Research Equipment

1a The Haymarket & 3 White Lion Street, Norwich, NOR 45E
Tel: Norwich 23696 & 26819

Stereoscopic Microscopy

- Constant working distance allowing adequate room for manipulation and dissection.
- Instant magnification changes by turning indexed drum.
- Uses transmitted or reflected light.
- Magnification range 3.6 × to 88 ×.
- Field of view from 42 mm to 2.6 mm.
- Measuring eyepiece and graticules.
- Universal stand has 8 in. rack and pinion horizontal movement.

Price £134 complete.
(or £125 without stand) 7 days delivery.

Our Advisory Department will gladly answer your enquiries with regard to the suitability of this equipment for your specific uses. Furthermore, these instruments are available to you for 14 days without obligation in order that their versatility may be determined under your actual working conditions.

CLASSIFIED ADVERTISEMENTS are charged at 12s. for the first line and 6s. per line thereafter. Lines in capitals or containing words in capitals 12s. per line. Semi-displayed £4 16s. per single column inch. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, Estrand, London.

APPOINTMENTS VACANT

MONASH UNIVERSITY
MELBOURNE, AUSTRALIA
CHAIR OF PURE MATHEMATICS
AND CHAIR OF APPLIED MATHEMATICS

A second chair of pure mathematics and a second chair of applied mathematics have been established in the department of mathematics. There is also a chair of statistics in the department. In addition to undergraduate teaching, an energetic postgraduate programme by means of seminars and formal lecture courses is under way.

A CDC 3200 computer is shortly to be installed in the university, which already possesses a 4,000-word Ferranti Sirius computer. Interests in pure mathematics of the present members for the department lie in the fields of algebra, topology, functional analysis and mathematical logic. Applicants for the new chair of pure mathematics should preferably have interests which lie principally in one or more of these fields.

It is hoped that prospective applicants for the chair of applied mathematics will have research interests connected with one or more of the fields of partial differential equations, fluid mechanics, plasma physics, and astronomy. It is not, however, intended to exclude from consideration applicants with experience in other fields. In statistics, current research is in the fields of probability and stochastic processes. Present arrangements are that the department is administered by a chairman, the chairmanship being held, for a three-year period, by the professors in rotation.

Salary: £A4,600 per annum (under review). Superannuation on F.S.S.U. basis.

Information on application procedure, conditions of appointment, etc., is available from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or from the Registrar, Monash University, Clayton, Victoria, Australia. Closing date: November 30, 1964.

The Council reserves the right to make no appointment, or to appoint by invitation at any stage.

VICTORIA UNIVERSITY OF WELLINGTON
NEW ZEALAND
SENIOR LECTURER IN GEOPHYSICS

Applications are invited for the above-mentioned post. Candidates should have had experience as applied geophysicists and preference will be given to one with a strong background in Geology. The salary will be £2,100 per annum rising to £2,500 per annum, initial salary being determined according to qualifications and experience. Approved fares to Wellington will be allowed for an appointee, his wife and his dependent children; in addition, actual removal expenses will be allowed within specified limits.

Further particulars and information as to the method of application should be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. Applications close in New Zealand and London on October 16, 1964.

RESEARCH CHEMIST

Young, well qualified organic chemist, preferably with a Ph.D. degree required for a modern well-equipped research laboratory in Central London, engaged on research in medicinal and natural and synthetic compounds. Apply to the Managing Director, with full particulars of age, education and salary anticipated. Non-contributory Pension and Life Assurance Scheme.

Biorex Laboratories Ltd., 47/51 Exmouth Market, London, E.C.1.

Tobacco Chemistry

Gallaher Limited invite applications for two posts for their Central Laboratories in Belfast. These involve the study of the composition of tobacco leaf and tobacco smoke and their inter-relationship. For both the positions applicants should be aged 23-28 and have a good Honours degree with subsequent research experience. This experience may have been gained either at University or in Industry.

For one post a special interest in Plant Bio-Chemistry would be valuable. For the other position, it is desirable for the candidate to have experience in the application of one or more of the following techniques—Gas Chromatography, Ultra Violet Absorption and Emission Spectrometry, Infra-Red Spectrometry.

Both the successful applicants will join a team in the Central Laboratory where there are good prospects for a man of initiative who has a practical outlook coupled with versatility.

The salary will depend on age and experience and will be subject to annual review. The Company operates a contributory pension and life assurance scheme.

Applications, in confidence, giving personal details and describing education, qualifications and experience should be addressed to

The Chief Chemist,
Gallaher Limited
Henry Street, Belfast, 15

ARTHUR D. LITTLE LTD.

Sensory Measurement: Odour and Taste

Applications are invited from men or women graduates with training in organic chemistry and some branch of biology, and preferably with about five years industrial or university research experience. An interest in sensory measurement and in contacting user organizations is essential.

The successful applicant, after a period of training in the U.S.A., will be required to build up and lead a group responsible for the assessment of odour and flavour as a service to the food and other industries.

Applications, setting out full personal details, should be addressed to the Secretary, Arthur D Little Ltd., Inveresk Gate, Musselburgh, Midlothian.

CHEMIST OR BIOCHEMIST WITH INTEREST in proteins to carry out fundamental research into the molecular structure of collagen. The work will be carried out under a grant from the Agricultural Research Council. Persons who have graduated this year will be considered. The laboratories are moving to Birmingham in 1965.—Applications to the Director of Research, The Gelatine and Glue Research Association, 2a Dalmeny Avenue, Holloway, London, N.7.

SENIOR ASSISTANT IN RESEARCH, OR Assistant in Research, to work on the micro-palaeontology of deep-sea sediments, with opportunities for work at sea, commencing October 1964, or not later than January, 1965, for three years. Salary scales £1,400 by £85 to £1,995; and £1,000 by £50 to £1,050 by £75 to £1,350, respectively.—Applications to, and further information from, the Secretary, Department of Geology, Downing Street, Cambridge.

AARONS, I. : Renal Immunofluorescence in *NZB/NZW* Mice, 1080
Abeyounis, C. J., et *al.* : Homotransplantation Antibodies detected by Mixed Agglutination with Cell Culture Monolayers, 313
Aboav, D. A., and Andrade, Prof. E. N. da C. : Grain Growth in Cadmium, 635
Abortion of Ewes : Enzootic (M. J. Studdert and P. C. Kennedy), 1088
Abraham, G., et *al.* : Non-enzymatic Interactions of Reduced Coenzyme I with Inorganic Phosphate and Certain other Anions, 973
Abrahams, Dr. V. C., et *al.* : Potentials evoked in the Hypothalamus and Cerebral Cortex by Electrical Stimulation of the Uterus, 654
Absorption Spectrum of the Crystal of *D*-Amino-acid Oxidase Michaelis Complex (Prof. K. Yagi and T. Ozawa), 864
Acanthocephala in the Intestines of Freshwater Fish : Evidence for a Dynamic Equilibrium in the Incidence of Cestoda and (Dr. J. C. Chubb, et *al.*), 986
Accelerating and Inhibiting Effects of Crowding on Sexual Maturation in Two Species of Locusts (M. J. Norris), 784
Acclimatization at 19,000 ft. : Falling Efficiency at Sorting Cards during (M. B. Gill, et *al.*), 436
Acclimatization to Heat in Physically Fit Subjects : Lack of Artificial (Dr. J. E. Greenleaf), 1072
Acetoin by Myo-inositol-deficient Yeast : Accumulation of (Prof. L. M. Lewin and E. J. Smith), 867
N-Acetyl Aspartic Acid in the Brain : Function of, Effects of Certain Drugs (J. C. McIntosh and Prof. J. R. Cooper), 658
Acetylcholine on Motor-nerve Terminals : Direct Evidence for an Action of (Dr. J. I. Hubbard and Dr. T. Yokota), 1072
Acetylcholine Receptors in Muscle Membrane (Prof. A. Portela, J. C. Pérez, M. Luchelli, Prof. P. Stewart and E. Strajman), 1179
Achondrites : Electron Microprobe Analysis of the Metallic Phase in Basic (Dr. J. F. Lovering), 70
Acid, Ammonium and Nitrate Distribution in Grasses (H. W. Dougall and Prof. H. F. Birch), 1308
Acid Hydrolysis or by Sialidase : Urinary Trypsin Inhibitor (Mingin) : Transformation into a new Trypsin Inhibitor by (Dr. T. Astrup and U. Nissen), 255
Acid Invertase-levels in Sugar Cane Stalks by Auxin- and Metabolite-mediated Control Systems : Regulation of (Dr. K. T. Glasziou and J. C. Waldron), 541
Acid-labile Ribose as an Indicator of Ribonucleic Acid Base Composition (D. I. Eddy), 186
Acid Phosphatases from Plant Sources : Specificities of Several (T. Ikawa, Prof. K. Nisizawa and Prof. T. Miwa), 939
Acid Secretion : Concentration of Ammonia in the Gastric Venous Blood of Dogs during (G. V. Shead and Prof. H. D. Ritchie), 1073
Acid and Uptake of Oxygen by Gastric Mucosa of the Frog : Effect of Thiocyanate on Secretion of (W. H. Bannister), 978
Acidic Media : Release of Cores from Bacterial Spores by Mechanical Breakage in (A. D. Hitchins and Dr. G. W. Gould), 895
Acidic Solutions : Production of Gallium by Continuous Electrodeposition from (Dr. R. L. Stearns), 749
Acidophilia of Aortic Elastin in the Child (D. W. Menzies, G. B. Ryan and J. T. Roberts), 195
Acoustic Behaviour of *Pholidoptera* : Inhibition and Excitation in the (M. D. R. Jones), 322
Actin in the Fibrous Form from Fish Muscle : Direct Extraction of (Dr. G. N. Graham), 405
Actinomycin *D* : Inhibition of Ovulation in the Rabbit by (W. R. Pool and Prof. H. Lipner), 1385
  Time-dependent Inhibition of Myogenesis by (Dr. P. Pietsch), 1177
Actinomycin *D* on Measles Virus Growth and Interferon Production : Effect of (C. D. Anderson and Dr. J. G. Atherton), 671
Actinomycin *D* and Messenger-RNA Turnover (Dr. A. C. Trakatellis, Prof. A. E. Axelrod and Dr. M. Montjar), 1134
Actinomycin *D* and Ribonuclease : an Example of Complementary Inhibition : Combination Chemotherapy with (Prof. A. C. Sartorelli), 877
Actomyosin : A New Protein Factor promoting Contraction of (Prof. S. Ebashi, et *al.*), 645
Adams, P. R., et al. : Inhibitory Effect of Progesterone on Activity of Human Myometrial Adenosine Triphosphatase, 83
Adenine by a Mutant of *Candida utilis* : Utilization of (Dr. G .R. Barker and V. Jechová), 189
Adenine and Guanine on Hepatic Glucose Release and on the Action of Insulin on the Liver : Effects of (A. Kaldor, Z. El Baz Rihan, T. R. Nichols and Prof. W. J. H. Butterfield), 1186
3′,5′-Adenosine Monophosphate : Stimulation of Steroid C-11β Hydroxylase Activity in Adrenal Homogenates by Cyclic (Prof. S. Roberts, et *al.*), 759
Adenosine Triphosphatase in the Myoepithelial Cells of Rat Salivary Glands : Histochemical Localization of Alkaline Phosphatase and (M. Shear), 770
Adenosine Triphosphate-creatine Phosphotransferase : Amino-acid Sequence Around the Reactive Thiol Groups of (Dr. A. R. Thomson, et *al.*), 267
Adenosine Triphosphate Deficiency : Biochemical Pathology of Acute Hepatic (Prof. E. Farber et *al.*), 34
Adhesive Disk of *Echenesis naucčates* (B. Bonnell), 206
Adhesive Tape : Identification of the Bacteriostatic Component of 'Scotch' Brand of Cellulose (J. W. May and R. H. Houghton), 100
Adipose Tissue : Effect of Aminonucleoside and Puromycin on Insulin and Epinephrine Control of Fatty Acid Release from (Dr. A. Korner and Dr. M. S. Raben), 1287
Adipose Tissue Homogenates : Stimulation of Glucose Utilization by Insulin in Human (A. Kahlenberg and Dr. N. Kalant), 83
***Administrators* : *The Reform of the Civil Service* (Fabian Tract No. 355), 555**
Adrenal Glands in Vitamin E Deficiency : *in vitro* Corticoid Synthesis by Quartered Adrenal Glands of Rats deprived of Vitamin E (Dr. A. E. Kitabchi), 650
Adrenal Homogenates by Cyclic 3′,5′-Adenosine Monophosphate : Stimulation of Steroid C-11β Hydroxylase Activity in Adrenal Homogenates by Cyclic (Prof. S. Roberts, et *al.*), 759
Adrenal Medulla : Stimulant Action of Barium on the (Prof. W. W. Douglas and Dr. R. P. Rubin), 305
Adrenal Steroid 11β-Hydroxylase : An Inhibitor of (Dr. M. L. Givner, et *al.*), 317
Adrenaline : Rapid Action of Hydrocortisone on the Increase in Blood Glucose after (T. D. R. Hockaday), 1242
Adrenocortical Insufficiency to Spontaneous Regression in Mammary Tumours induced in Rats by Oral Administration of Dimethylbenzanthracene : Relationship of (Dr. S. Young, J. E. Helfenstein and R. A. Baker), 1079
Advancement in Coke Technology (Prof. R. J. Sargant), 585
Advancement of Scientific Education in Schools, 27
Advances in Analytical Chemistry and Instrumentation, Vol. 2 (edited by Charles N. Reilley), *review* by R. J. Mesley, 442
Advances in Photochemistry, Vol. 1 (edited by W. Albert Noyes, jun., G. S. Hammond and J. N. Pitts, jun.), *review* by Dr. H. M. Frey, 225
Aerobacter aerogenes : Relationship between the Products of Aromatic Biosynthesis in *Mycobacterium smegmatis* and (Dr. C. Ratledge), 428
Aflatoxins : Determination of the (J. Nabney and Dr. B. F. Nesbitt), 862
Age of Advice (E. Rea), 954
Age of Caledonian Orogeny and Metamorphism in Britain (F. J. Fitch, Dr. J. A. Miller and Dr. P. E. Brown), 275
Age of Labrador Anorthosites (Dr. S. A. Morse), 509
Age of the Newgale Beds (H. G. Davies and Dr. C. Downie), 71
Aging Eye (Dr. R. A. Weale), *review* by Dr. M. H. Pirenne, 1209
Ageing and Noise in the Visual System (Prof. M. A. Jeeves), 435
Ager, Dr. D. V. : The British Mesozoic Committee, 1059
Agglutination with Cell Culture Monolayers : Homotransplantation Antibodies detected by Mixed (C. J. Abeyounis et *al.*), 313
Agnihotri, O. P. : 'Hook Effect' in the Analysis of X-ray Diffraction Line Profiles, 177
Agricultural Research Council Unit of Nitrogen Fixation, 576
Agricultural Soil Science (R. I. Davies), 133
Agropyron repens L. Beauv. : Influence of Nitrogen Nutrition on Bud and Rhizome Development in (G. L. McIntyre), 1084
Aims and Objectives in Expanding Higher Education, 107
Air : Radiative Detonation Model for the Development of a Laser-induced Spark in (S. A. Ramsden and P. Savic), 1217
Aisen, Dr. P., et *al.* : Biliary Excretion of Cæruloplasmin Copper, 873
Aitken, Dr. J. T., and Gwyn, Dr. D. G. : New Motor End-plates and their Relationship to Muscle Fibre Injury, 561
Akiyama, T., and Keii, Prof. T. : Role of Grinding of Titanium Trichloride in Natta's Polymerization, 76
AKR Thymocytes : Immunological Distinction of (Prof. A. E. Reif and Mrs. J. M. V. Allen), 886

Allen, Mrs. J. M. V., and Reif, Prof. A. E. : Immunological Distinction of *AKR* Thymocytes, 886
Allison, Dr. A. C., and Mallucci, Dr. L. : Uptake of Hydrocarbon Carcinogens by Lysosomes, 1024
Allocation of Frequencies for Radio Astronomy and Space Science (Dr. R. L. Smith-Rose), Substance of a paper presented at the Seventh Plenary Meeting of the International Committee on Space Research (COSPAR), 1964, 7
Allotropes of Sulphur and the α-γ Transition Point : Vapour Pressure Equations and Melting Points of (M. Thackray), 1278
Alloy Synthesis : Low-temperature (E. L. Holt), 857
Alloys, Sintering-Cobalt-Chrome-Molybdenum, for Osteosynthesis (Dr. J. M. Zarek *et al.*), 900
Alouette I : Recordings from Satellite (N. M. Brice *et al.*), 926
Alpert, Dr. S., *et al.* : Biliary Excretion of Cæruloplasmin Copper, 873
α_2-Globulin during the Inflammatory Response of the Rat : Appearance of Slow (Prof. W. G. Heim and P. H. Lane), 1077
Alpha$_2$-Globulin of Rat Serum : Slow (G. A. Boffa *et al.*), 1182
Altitudes : Simultaneous Sampling at Different (Prof. V. D. Hopper *et al.*), 289
Altschul, Dr. A. M., *et al.* : A New Classification of Seed Proteins : Application to the Aleurins of *Arachis hypogaea*, 501
Amborski, Dr. G. F., and Moskowitz, Prof. M. : Nutritional and Physical Factors affecting the Aggregation of Cultured Mammalian Cells, 1236
American Documentation Institute, annual meeting, 920, 1124
American Philosophical Society, *Year Book* 1963, 459
American Society for Cell Biology, fourth annual meeting, 1337
American Society of Plant Physiologists : awards, 1124
American Society for Testing and Materials (Dr. R. F. Legget), 565
Amines to Bovine Serum Albumin : Enthalpy of Binding of Aromatic (M. R. V. Sahyun), 1045
D-Amino-acid Oxidase Michaelis Complex : Absorption Spectrum of the Crystal of (Prof. K. Yagi and T. Ozawa), 864
L-Amino-acid Oxidase Specificity : Electronic Effects and (Dr. G. K. Radda), 936
Amino-acid Sequence around the Reactive Thiol Groups of Adenosine Triphosphate-creatine Phosphotransferase (Dr. A. R. Thomson, J. W. Eveleigh and B. J. Miles), 267
Amino-acid Transport and Protein Synthesis : Hormones (Dr. S. Segal), 17
Amino-acids : Improvements in the Single Column System : Ion-exchange Chromatography of (Dr. A. R. Thomson and B. J. Miles), 483
Amino-acids in Deoxyribonucleic Acid : A Suggested Role of (Dr. M. Earl Balis, J. S. Salser and A. Elder), 1170
Amino-acids into Protein in Cell-free Systems from *B. subtilis* : Action of Rifamycin on Incorporation of (L. Frontali *et al.*), 84
Amino-acids of the Aspartic Family : Alternative Patterns of End-product Control in Biosynthesis of (Dr. P. Datta and Prof. H. Gest), 1259
β-Aminoethylisothiuronium (AET) Cl HCl and Homologous Testes-DNA on the Death-rate of the Progeny of a First Generation originating from Male Rats irradiated in the Infantile Period : Effect of Chemical Protective Agents Cysteamine and (Dr. N. Savkovič), 1393
2-Aminoethylphosphonic Acid in *Tetrahymena* : Distribution and Fate of (Dr. H. Rosenberg), 299
Aminonucleoside and Puromycin on Insulin and Epinephrine Control of Fatty Acid Release from Adipose Tissue : Effect of (Dr. A. Korner and Dr. M. S. Raben), 1287
6-Aminopenicillanic Acid : Hæmagglutination of Erythrocytes coated with (Dr. K. C. Watson), 412
4-[(-Amino-5-pyrimidinyl)-imino]-2-penten-2-ol. : Structural Investigation of (S. Chatterjee *et al.*), 970
Amir, S. M., *et al.* : Synthesis of Glucopeptides, 401
Ammonia in the Gastric Venous Blood of Dogs during Acid Secretion : Concentration of (G. V. Shead and Prof. H. D. Ritchie), 1073
Ammonia and Aliphatic Amines with Sulphur Dioxide : Reactions of (T. Hata and Prof. S. Kinumaki), 1378
Ammonium Halide Solutions : Proton Magnetic Relaxation Times of Aqueous Tetra Alkyl (Prof. S. S. Danyluk and E. S. Gore), 748
Ammonium Production in Soil under Waterlogged Conditions as an Index to Nitrogen Availability (S. A. Waring and Prof. J. M. Bremner, 201, 951), *erratum*, 819
Ammonium and Nitrite Distribution in Grasses : Acid, (H. W. Dougall and Prof. H. F. Birch), 1308
Amœbæ : Cytoplasmic Inheritance in : Nuclear Transfer Investigations (Dr. S. E. Hawkins), 95
Amorphous Films : Electrical Conduction in (Dr. C. Feldman), 964
Amorphous Structures : Metastability of (Prof. M. H. Cohen and Dr. D. Turnbull), 964
Amsinckia intermedia to the Interrelated Effects of Low Temperature, Thiamin and 2,4-Dichlorophenoxyacetic Acid : Formative Response of (W. G. Mauldin and Prof. T. J. Muzik), 427
Amundsen, E., *et al.* : Kininase Inhibition by a Fluorescent Substance prepared from Liver, 1245
Amyloid : Protein Components of (T. J. Muckle), 773
Anaerobic Growth of *Staphylococcus* : Effect of Hæmin Supplementation on Porphyrin Accumulation and Catalase Synthesis during (Dr. R. E. Heady, *et al.*), 1285
Analysis of Algal Pigments by Thin-layer Chromatography (Dr. J. S. Bunt), 1261
Analysis Instrumentation—1963 (edited by Dr. L. Fowler, R. D. Eanes and T. J. Kehoe) : Proceedings of the Ninth National Analysis Instrumentation Symposium, April 1963), *review* by C. O. Harvey, 906
Analysis of Petroleum for Trace Elements (O. I. Milner), *review* by E. Thornton, 685
Analyses of Radionuclides of Biological Interest in Pacific Waters (D. Chakravarti, G. B. Lewis, R. F. Palumbo and A. H. Seymour), 571
Analysis and Computation of Electric and Magnetic Field Problems (K. J. Binns and P. J. Lawrenson), *review* by E. M. Freeman, 225
Analytical Chemistry : Complexation in (Anders Ringbom), *review* by Dr. J. R. Cooke, 559
Analytical Chemistry in Nuclear Technology, eighth Conference on, 1018
Analytical Chemistry in the Interest of the Public (Dr. W. I. Stephen), 1229
Anaphylactic Reaction *in vitro* : Effect of Excess of Antigen on the Active (Dr. A. Prouvost-Danon and M. Queiroz da Cruz), 876
Ancient Iraq (Georges Roux), *review* by T. K. Penniman, 802
Ancient and Medieval Science from Prehistory to A.D. 1450 (edited by René Taton), *review* by Dr. Mary Hesse, 111
Anderson, C. D. and Atherton, Dr. J. G. : Effect of Actinomycin *D* on Measles Virus Growth and Interferon Production, 671
Anderson, E. C. and Petersen, D. F. : Quantity Production of Synchronized Mammalian Cells in Suspension Culture, 642.
Anderson, Dr. J. M. and Boardman, Dr. N. K. : Isolation from Spinach Chloroplasts of Particles Containing Different Proportions of Chlorophyll *a* and Chlorophyll *b* and their Possible Role in the Light Reactions of Photosynthesis, 166
Anderson, Prof. J. S. : Noble Gas Compounds, *review*, 442
Anderson, M. M. and Nagle, Prof. C. W. : Effect of the Unsaturated Bond on the Degradation of the Tetragalacturonic Acids by a Transeliminase, 649
Anderson, W. M. and Robinson, B. E. : Metric to Inch Conversion, 551
Andrade, Prof. E. N. da C. : Early Recognition of Galileo's Work in England, 552
Andrade, Prof. E. N. da C., and Aboav, D. A. : Grain Growth in Cadmium, 635
Andrew, B. H., *et al.* : Radio Observations of the Crab Nebula during a Lunar Occultation, 171
Andrew, I. G. : Free Sugars in Spores of *Pithomyces chartarum*, 204
Andrews, Dr. J. R. and Correa, Dr. J. N. : Modification of the Radiation Effect on Ascitic Tumour Cells by Pharmacological Agents injected intravenously, 200
Andromeda Nebula, 577
Androsterone : Molecular Geometry of (Dr. D. A. Norton and J. M. Ohrt), 754
Angiosperm Taxonomy : Principles of (Dr. P. H. Davis and Dr. V. H. Heywood), *review* by Prof. J. Heslop-Harrison, 333
Angiospermous Plants : Specific Inhibition of Anti-Rh Antibodies by Extracts from Twigs of (Prof. G. F. Springer and Mrs. H. Tegtmeyer), 298
Angiotensin : Hepatic Inactivation of (Dr. A. L. Methot, *et al.*), 531
Anils : Effect of Substituents on Electrical Conductivity of (E. W. Gooden), 515
Animal Complex : Soil-Plant- (Dr. T. G. Taylor), 924
Animal Worlds (Marston Bates), *review* by Dr. L. Harrison Matthews, 907
Animals : Blood Velocity telemetered from Untethered (D. L. Franklin, *et al.*) 528
Anion Adsorption on Platinum by the Multipulse Potentio-Dynamic Method (S. Gilman), 1130
Anisotropy Field of Continuous Magnetic Films Subjected to Inhomogeneous Drive Fields : Apparent (J. G. Edwards), 710
Anisotropy of Friction in Crystals (Dr. F. P. Bowden, Dr. C. A. Brookes and A. E. Hanwell), 27
Anker, H. S. and Rennert, O. M. : Effect of 5′, 5′, 5′-Trifluoroleucine on a Number of Mouse Leukæmias, 1256
Annals of the New York Acdemy of Sciences, 698
Annual Review of Nuclear Science, Vol. 13 (edited by Emilio Segre), *review* by Dr. R. J. N. Phillips, 114
Annulus Formation, Segré-Silberberg : A Possible Explanation (R. V. Repetti and Prof. E. F. Leonard), 1346
Anodes in Acidic Oxalate Solutions : Optical Investigations of Film Formation and Removal on Gold (W. E. Reid and Dr. J. Kruger), 402
Anomalous Doppler Radiation and Very-low frequency Emissions (Prof. G. R. A. Ellis), 1271
Anomalous Reactions of the Rat to Ganglion Blocking Agents (Dr. J. M. Whyte), 307
Anopheles gambiae : Selection for Host Preference in (M. T. Gillies), 852
Giles from an Unsprayed Area in Northern Nigeria : A High Incidence of Dieldrin-resistance in (M. W. Service and G. Davidson), 209
Anopheles pseudopunctipennis in Mexiclo after Prolonged Use of DDT : Ethological Changes in (Prof. A. Martinez-Palacios and Dr. J. de Zulueta), 940
Anorthosites : Age of Labrador (Dr. S. A. Morse), 509
Anstis, Dr. S. M. : Apparent Size of Holes felt with the Tongue, 792
Anthelmintics in the Laboratory : *Trichostrongylus colubriformis* (a Nematode Parasite of Sheep and Other Ruminants) as a Test Organism in Screening for Sheep (G. A. H. Williams and B. H. Palmer), 1399
Anthropology, Canadian, 818
Anti-A Hæmagglutinin Response to Influenza Infection : Lack of (Dr. M. K. Fagerhol, A. Harboe and O. Hartmann), 1185
Anti-*D* by Human Urinary Mucoprotein : Specific Inhibition of (Dr. H. W. Johnson and M. C. Dodd), 1082
Antibacterial Interaction between Bromthymol Blue and Polymyxin B (Dr. F. D. Crisley), 211
Antibiotic Reactions between African Savanna Species (Prof. A. S. Boughey, P. E. Munro, Mrs. J. Meiklejohn, R. M. Strang and Dr. M. J. Swift), 1302
Antibiotic Sensitivity and Bacterial Numbers (Dr. D. Kaplan and Dr. W. Koch), 1091
Antibiotics, Increase of the Effectiveness of Polyene, with Univalent Cations (Dr. I. Horváth and I. Koczka), 1305
Antibiotics of *Alcaligenes faecalis* (Dr. I. J. Maré and Prof. J. N. Coetzee), 430
Antibodies on an Insoluble Support for Specific Detection of Radioactive Antigens : Use of (A. E. Gurvich and G. I. Drizlikh), 648
Antibody-forming Cells : Immunofluorescent Detection of Proliferating Human (P. Urso and Dr. N. Gengozian), 1391
Antibody Immunoassay for Human Growth Hormone in Plasma A Sensitive Double (Dr. D. S. Schalch and Dr. M. L. Parker), 1141
Antibody to Endotoxin with 6-Mercaptopurine : Suppression of : Effect of
7S Antibody and its Sub-units : Combination with Red Cells of Immune Rabbit (Dr. C. L. Greenbury, *et al.*), 1147
Anticerebral Antibodies on the Histamine-like Substance and Potassium Content of Various Regions of the Brain of the Cat : Effect of Intraventricularly Injected (Dr. Lj. Mihailović, *et al.*), 763
Anti-corrosion System : An Antifouling and (B. Wisely), 1132
Anti-fibrillatory Agent : Guanthidine as an (Prof. P. E. Leveque), 1389
Antifouling and Anti-corrosion System (B. Wisely), 1132
Antifungal Activity in Orange Tissue infected with *Aspergillus niger* (Dr. D. M. Spencer and G. A. Carter), 894
Antigen : Production of SV-40 Complement-fixing (Dr. K. R. Schell), 417
Antigen Dose (Dr. M. Rubentein and Dr. S. M. Wolff), 1390
Antigen Dose : Effect of : Suppression of Antibody to Endotoxin with 6-Mercaptopurine (Dr. M. Rubenstein and Dr. S. M. Wolff), 1390
Antigen on the Active Anaphylactic Reaction *in vitro* : Effect of Excess of (Dr. A. Prouvost-Danon and M. Queiroz da Cruz), 876

Antigenic Challenge : Proliferation of Transferred Spleen Cells after (Dr. M. J. Cohen and Dr. E. P. Cohen), 418
Antigenic Markers to Native Proteins : Use of Simple Gel-diffusion Techniques to Assign (Prof. I. Finger), 1035
Antigens Specific of Human Breast Carcinoma by an Immunochromatographic Method : Preparation of (Dr. S. DeCarvalho), 1186
Antihæmophilic Factor Concentrate prepared from Cryoglobulin Precipitate : High-potency (Dr. J. G. Pool, *et al.*), 312
Antihypertensive Effect of α-Methyldopa : Mechanism of the (Prof. R. Imaizumi, et *al.*), 982
Anti-Locust Research Centre, London (Dr. P. T. Haskell), 233
Animal Tissues : Reduction of Dehydroascorbic Acid by (Dr. R. E. Hughes), 1068
Antimicrobial Agents and Chemotherapy, fourth interscience conference, 1228
Antimonides of Niobium : Arsenides and (S. Furuseth and Prof. A. Kjekshus), 512
Antioxidants in Oats : Light-induced isomerization (Dr. D. G. H. Daniels and H. F. Martin), 299
Antioxidants isolated from Fermented Soybeans (Tempeh), (Prof. P. György, Prof. K. Murata and Dr. H. Ikehata), 870
Anti-Rh Antibodies by Extracts from Twigs of Antiospermous Plants : Specific Inhibition of (Prof. G. F. Springer and Mrs. H. Tegtmeyer), 298
Antitoxins : Co-precipitating Properties of 3 S Fragments derived from Horse (Prof. M. Raynaud and S. Iscaki), 759
Aortic Elastin in the Child : Acidophilia of (D. W. Menzies et *al.*), 195
Apical Dominance in Plants : Mechanism of (G. I. McIntyre), 1190
Apis mellifera L. : Secretory Activity in the Corpora Allata of Worker Honey-bee (Dr. J. E. J. Habowsky and W. E. Beckel), 1090
Apparent Size of Holes felt with the Tongue (Dr. S. M. Anstis), 792
Apple Cuticle : Wax and the Water Vapour Permeability of (R. L. Horrocks), 547
Apple Scions : Relation of Electrical Resistance to Vigour of (Prof. C. D. Taper and R. S. Ling), 782
"Application of Chemical Engineering in Newly Developing Countries", symposium, 700
Aqueous Solution : A Kinetic Approach to the Nature of Ferrous Ions in (Dr. C. F. Wells and M. A. Salam), 751
Aqueous Solutions by the Attenuated Total Reflectance Technique : Infra-red Spectra of (Dr. J. D. S. Goulden and D. J. Manning), 403
Arabia Felix : The Danish Expedition of 1761–1767 (Thorkild Hansen), *review* by Prof. C. F. Beckingham, 441
Arachis hypogaea : A New Classification of Seed Proteins : Application to the Aleurins of (Dr. A. M. Altschul et *al.*), 501
Arboviruses in East Africa : Bats and (M. C. Williams et *al.*), 670
Arcamone, F., et *al.* : Structure and Synthesis of Distamycin A, 1064
Argon Atoms : Anomalous Ionization of Methyl Linolenate by Metastable Argon Atoms : Possible Linolenic Acid Participation in Photosynthetic Reactions (A. G. Vereshchagin and G. V. Novitskaya), 1384
Arias, Dr. I. M., and Gartner, Dr. L. M. : Production of Unconjugated Hyperbilibrubinæmia in Full-term New-born Infants following Administration of Pregnane-3(alpha),20(beta)-diol, 1292
Armitage, Prof. P. : Méthodes Statistiques à l'Usage des Médecins et des Biologistes, *review*, 686
Aromatic Biosynthesis in *Mycobacterium smegmatis* and *Aerobacter aerogenes* : Relationship between the (Dr. C. Ratledge), 428
Arridge, R. G. C., and Prior, K. : Cooling Time of Silica Fibres, 386
Arsenides and Antimonides of Niobium (S. Furuseth and Prof. A. Kjekshus), 512
Art of Calligraphy, 1230
Artefactual Chromatid Aberrations in Untreated and X-ray-treated Human Lymphocytes (Dr. B. R. Migeon and Dr. T. Merz), 1395
Arthrodiran Anatomy (Dr. H. P. Whiting), 1023
Artificial Acclimatization to Heat in Physically Fit Subjects : Lack of (Dr. J. E. Greenleaf), 1072
Artificial Heterogenization of Tumours by means of Herpes Simplex and Polyoma Viruses (V. P. Hamburg and Dr. G. J. Svet-Moldavsky), 772
Arvicola amphibius : *Leptospira erinacei auriti* in a Water vole (G. Slavin *et al.*), 893
Asatoor, A. M. : Pyridoxine Deficiency in the Rat Produced by D-Penicillamine, 1382
Ascaris lumbricoides : Hyperpolarizing Action Protentials recorded from the œsophagus of (Prof. J. Del Castillo et *al.*), 530
Ascitic Tumour Cells by Pharmacological Agents injected intravenously : Modification of the Radiation Effect on (Dr. J. N. Correa and Dr. J. R. Andrews), 200
Ascospores of *Ophiobolus graminis* : Infection of Wheat Roots by (D. H. Brooks), 203
Asellus (Crustacea, Isopoda) in Esthwaite and Ullswater, English Lake District : Occurrence of (Prof. H. P. Moon), 894
Ashton, B., and Sevag, Prof. M. G. : Evolution and Prevention of Drug-resistance, 1323
Aslib annual conference, 700
Aspartic Family : Alternative Patterns of End-product Control in Biosynthesis of Amino-acids of the (Dr. P. Datta and Prof. H. Gest), 1259
Aspects of Marine Fisheries Research (Dr. C. E. Lucas), 950
Aspens (Prof. S. A. Graham, R. P. Harrison and C. E. Westell, jun.), *review* by Dr. F. N. Howes, 1005
Aspergillus fischeri var. glaber : A $C_{15}H_{22}O_4$ Compound produced by the Fungus (J. J. Ellis et *al.*), 1382
Aspergillus nidulans : Physiological and Genetic Effects of 8-Azaguanine on (Dr. A. T. Bull and Dr. B. M. Faulkner), 506
Aspergillus niger : Antifungal Activity in Orange Tissue infected with (Dr. D. M. Spencer and G. A. Carter), 894
Aspergillus niger van Tiegh : Metabolism of 2,4-Dichlorophenoxyacetic Acid ('2,4-D') by (J. K. Faulkner and Dr. D. Woodcock), 865
Metabolism of Phenoxyacetic Acid by (D. R. Clifford and Dr. D. Woodcock), 763
Asplenium : Autopolyploidy in (Dr. J. D. Lovis), 324
Astbury, Dr. N. F. : Progress in Ceramic Science, Vol. 3, *review*, 804
Asteroxylon mackiei K. and L. : Probable Fertile Region of (Dr. A. G. Lyon), 1082
Astronautical Congress, fifteenth international, 240
Astronomer : Dr. R. M. Petrie appointed Dominion, 696
Astronomical Convention, Second National Amateur, 350
Astrup, Dr. T., and Nissen, U. : Urinary Trypsin Inhibitor (Mingin) : Transformation into a New Trypsin Inhibitor by Acid Hydrolysis or by Sialidase, 255
Asymmetry of Jupiter's van Allen Belt : Evidence for (J. A. Roberts and M. M. Komesaroff), 827
Atherosclerosis in Cholesterol-fed Rabbits : Deoxycorticosterone Acetate and Experimental (Dr. G. B. Rossi et *al.*), 252
Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs : Failure to induce (Dr. G. B. Rossi *et al.*), 416
Atherton, Dr. J. G., and Anderson, C. D. : Effect of Actinomycin *D* on Measles Virus Growth and Interferon Production, 671
Atlantic Ocean in July 1963 : Evidence of a South Equatorial Counter-current in the (J. L. Reid, jun.), 182
Atlas of Electron Microscopy (complied by F. Scanga), *review* by Prof. R. D. Preston, 1103
Atmosphere : Laser Radar Echoes from a Stratified Clear (R. T. H. Collis et *al.*), 1274
Atomic Structure and Chemical Bonding (Fritz Seel), *review* by Dr. D. J. Millen, 114
Aubert, Prof. X., and Keynes, Dr. R. D. : Energetics of the Electric Organ, 261
Auckland Islands, 26
Auditory Illusion of Distance (Dr. R. A. Butler and Dr. R. F. Naunton), 1201
Augenstein, L., and Nag-Chaudhuri, J. : Energy Transfer in Proteins, 1145
Auroral Absorption Event at Lower Latitude : Heights of Central Absorbing Regions for a Strong (Prof. J. S. Kim and J. D. Kleinkopf), 1160
Auroral Rays (F. R. Bond), 1275
Auroral Zone : Periodic Precipitation of the Particle Flux in the (Dr. R. N. Singh), 69
Austin, S., et *al.* : Incorporation of Fall-out Strontium-90 in Deciduous Incisors and Fœtal Bone, 615
Simultaneous Electromagnetic Measurement of Blood Flow in the Major Coronary Arteries, 148
Australian Academy of Science, Senior Fellowships for Short-term visits to, 128
Australian Association of Clinical Biochemists : Election of officers, 1018
Australian Defence Standards Laboratories (S. Weintroub), 25
Australian Mineral Industry **16**, No. 3, March 1964, 699
Australian Natural History, **14**, No. 10 ; June 1964, 1226
Australian Science Index, April 1964, **8**, No. 4, 819
Autogeny and Oviposition in Arctic Mosquitoes (P. S. Corbet), 669
"Automatic Methods of Analysis", meeting, 819
Automation, Leisure and Youth Services, 921
Autopolyploidy in *Asplenium* (Dr. J. D. Lovis), 324
Autoradiography : Tetrad Analysis by (K. M. Marimuthu and Prof. S. F. H. Threlkeld), 101
Auxin- and Metabolite-mediated Control Systems : Regulation of Acid Invertase-levels in Sugar Cane Stalks by (Dr. K. T. Glasziou and J. C. Waldron), 541
Aviation Research, 816
Awachie, Dr. J. B. E., et *al.* : Evidence for a Dynamic Equilibrium in the Incidence of Cestoda and Acanthocephala in the Intestines of Freshwater Fish, 986
Axelrod, Prof. A. E., et *al.* : Actinomycin *D* and Messenger-RNA Turnover, 1134
Axelrod, Dr. J., et *al.* : Neural and Photic Regulation of 5-Hydroxytryptophan Decarboxylase in the Rat Pineal Gland, 981
β-Axon Stimulation : Excitation of Primary Muscle Spindle Endings by (Dr. G. L. Kidd), 1248
Axotobacter chroococcum : Role of Cobalt in Nitrogen Fixation by (Dr. V. Iswaran and Dr. W. V. B. Sundara Rao), 549
Ayers, J. E., et *al.* : Off-flavour of Dehydrated Carrot stored in Oxygen, 81
Ayscough, Dr. P. B., et *al.* : Effect of Micro-crystal Formation on the Electron Spin Resonance Spectra of $\alpha\alpha$-Diphenyl-β-picrylhydrazyl in Various Frozen Solvents, 1378
8-Azaguanine on *Aspergillus nidulans* : Physiological and Genetic Effects of (Dr. A. T. Bull and Dr. B. M. Faulkner), 506
Azo Dye Carcinogens : Contact Reactivity to (Dr. J. Gordon), 884
Azotobacter Inoculation and Application of Gibberellins : Similar Effects on Tomato Plants of (Dr. R. M. Jackson et *al.*), 851

BACHI, C., et *al.* : Proliferation and Maturation Defect in Acute Leukæmia Cells, 92
Bacillus subtilis : Action of Rifamycin on Incorporation of Amino-acids into Protein in Cell-free Systems from (L. Frontali et *al.*), 84
Relation of Ribonucleic Acid Composition to Growth Rate and Dormancy in (Prof. R. H. Doi and R. T. Igarashi), 1092
Time of Synthesis of Deoxyribonucleic Acid and Protein in Spores of (Dr. R. E. Canfield and Dr. J. Szulmajster), 596
Bacq, Prof. Z. M., and Alexander, Dr. P. : Importance for Radio-Protection of the Reaction of Cells to Sulphydryl and Disulphide Compounds, 162
Bacteria : Effect of Deuterium on Starving (S. Lovett), 429
Effect of Magnesium on Permeability Control in Chilled (R. E. Strange), 1304
Enumerating Viable (Dr. W. Koch and Dr. D. Kaplan), 896
Rhythmic Alternations in the Rate of Synthesis and the Composition of Rapidly Labelled Ribonucleic Acid during the Synchronous Growth of (Dr. R. Rudner et *al.*), 479
Bacteria and their Mutants with Impaired Respiration : Deoxyribonucleic Acid Base Composition in Certain (G. G. Gause et *al.*), 598
Bacterial O Antigen from Rabbit Erythrocytes : Dissociation of (Prof. C. N. Shumway), 1081
Bacterial Benzyl Penicillin-splitting Enzyme : Variety of Substrates for a (Dr. W. Kaufmann and K. Bauer), 520
Bacterial Cross-resistance involving Penicillins, Chloramphenicol and Tetracycline : Development *in vitro* of (R. Sutherland et *al.*), 548
Bacterial Enzyme Synthesis by Induction and Repression : Regulation of (P. H. Clarke and W. J. Brammar), 1153
Bacterial Numbers : Antibiotic Sensitivity and (Dr. D. Kaplan and Dr. W. Koch), 1091
Bacterial Spores by Mechanical Breakage in Acidic Media : Release of Cores from (A. D. Hitchins and Dr. G. W. Gould), 895
Bacteriophage *TI* in the Shore Crab *Carcinus maenas* : Secondary Immune Response to (A. E. Taylor *et al*), 775
Bacteriophages : Host-range of Temperature *Serratia marcescens* (H. E. Prinsloo and Prof. J. N. Coetzee), 211
Bacteriostatic Component of 'Scotch' Brand of Cellulose Adhesive Tape : Identification of the (J. W. May and R. H. Houghton), 100
Baghdiantz, Dr. A., et *al.* : Extraction and Purification of Calcitonin, 1027
Bagley, E. D., et *al.* : Fracture of Liquids in Shear, 175
Baird, D. M. : *Geology and Landforms as Illustrated by Selected Canadian Topographic Maps*, 1227
Baker, A. de C. : Marine Distributions, *review*, 226

Butterworth, Dr. K. R. : Mechanism of Reversal of the Vasomotor Effect of Isoprenaline, 1291
Butterworths : Nuclear Magnetic Resonance Current Literature Service, 919
Byrne, Dr. J. G., and Wright, Prof. W. : Stress Concentration in Concrete, 1374

(C-N-O) RADICAL : Ultra-violet Absorption Spectrum of the Free Fulminate (Dr. W. D. McGrath and T. Morrow), 619
Ca^{++} : DNA Polymerase in Thymus Nuclear Fractions isolated with (Dr. R. K. Main and L. J. Cole), 646
Cadmium : Grain Growth in (Prof. E. N. da C. Andrade and D. A. Aboav), 635
Cæruloplasmin Copper : Biliary Excretion of (Dr. P. Aisen et *al.*), 873
Caesar, A. A. L. : Planning and the Geography of Great Britain, 950
Cæsium-Choline Interactions in Muscle Membrane : Potassium Effects on (Prof. A. Portela et *al.*), 1071
Cæsium-137 Content of Man due to Radioactive Fall-out, 1962–64 : Increase in the (Dr. J. Rundo and D. Newton), 537
Cæsium-137 Fall-out Body Burdens, Time Variation and Frequency Distribution (W. H. Ellett and Dr. G. L. Brownell), 53
Cæsium-137, Rhodium-102 and Manganese-54 in Surface Air : Concentrations of (P. F. Gustafson, S. E. Muniak and S. S. Brar), 470
Cages, Danger of Spraying Wood Insect, with Melamine Resins (Dr. T. A. M. Nash and R. J. Kernaghan), 1195
Calcite using Optically Active Etchants : Production of Dislocation Etch Pits on (Dr. J. M. Thomas et *al.*), 72
Calcitonin : Extraction and Purification of (Dr. A. Baghdiantz et *al.*), 1027
Calcitonin Production and the Mitochondrion-rich Cells of the Dog Thyroid (Dr. G. V. Foster, Dr. I. MacIntyre and Dr. A. G. E. Pearse), 1029
Calcium Fluoride : Slip and Polygonization during Crystal Growth (Dr. B. Cockayne, D. S. Robertson and B. W. Straughan), 1376
Calder, Prof. R. : The Western Invasions of the Pacific and its Continents, *review*, 560
Caledonian Orogeny and Metamorphism in Britain : Age of (F. J. Fitch et *al.*), 275
Calf's Spleen : Effect on Leukæmic Cells of Ribonucleic Acid extracted from (Prof. S. Esposito), 1078
Callantine, M. R., and Bass, Dr. P. : Simultaneous Recording of Electrical and Mechanical Activity of the Uterus in the Unanæsthetized Animals, 1367
Calligraphy : The Art of, 1230
Calorimetric Dose Measurements with 35-MeV Betatron Electron Radiation (J. Nagl, A. Sanielevici and R. Wideröe), 632
Campbell, Dr. B. G. : Science and Human Evolution, 448
Campbell, Prof. J. W., and Lee, Dr. T. W. : DNA, PNA and Protein Contents in a Rapidly Differentiating System, the Rat Tapeworm (*Hymenolepis diminuta*), 661
Canadian Department of Mines and Technical Surveys : Director of Observatories Branch appointed, 696
Canadian Embassy : Scientific Counsellor appointed to Embassy in Paris, 128
Canadian Journal of Earth Sciences, 1227
Canadian Society for Plant Physiologists (Dr. R. G. S. Bidwell), 242
Canalization : Mutant Expression and (Dr. W. Scharloo), 1095
Cancer in Man : Unusual Forms and Aspects of (Dr. F. J. C. Roe), 356
Candela, Prof. J. L. R.-, et *al.* : Effect of Glucose on Insulin Secretion *in vitro* by Rabbit Pancreas pre-incubated with β-Hydroxybutyrate, 758
Candida utilis : Utilization of Adenine by a Mutant of (Dr. G. R. Barker and V. Jechová), 189
Canfield, Dr. R. E., and Szulmajster, Dr. J. : Time of Synthesis of Deoxyribonucleic Acid and Protein in Spores of *B. subtilis*, 596
Cannon, Dr. P., and Norton, Dr. F. J. : Reaction between Molybdenum Disulphide and Water, 750
Cano-Ruiz, J., et *al.* : Temperature Variation of β-Type Interlamellar Sorption Complexes of Graphite Acid with Alcohols, 1063
Capey, W. D., et *al.* : Isotope Effect in Radical Reactions, 294
Capildeo, Dr. R. : Gravity and Rotation, 175
Capture of Low-energy Electrons in Chlorobenzene and Bromobenzene (Dr. J. E. Lovelock), 1267 ; (Dr. R. S. Becker and Prof. W. E. Wentworth), 1267 ; (Dr. J. A. Stockdale, Dr. G. S. Hurst and Dr. L. G. Christophorou), 1267
Carbohydrate Diets : Changes in the Fatty Acid Composition of Sebum associated with High (Dr. I. Macdonald), 1067
Carbon Dioxide : Occurrence of Urinary Calculi in Rats exposed to High Concentrations of Oxygen with Added (Prof. C. W. Smith and F. A. DeClement) 85
Carbon Dioxide Efflux from the Human Cornea *in vivo* (Prof. I. Fatt, Dr. R. M. Hill and Dr. G. H. Takahashi), 738
Carbon Dioxide and Cell Division (Dr. C. Sorokin), 1252
Carbon, Sources of, for Synthesis and the Fate of the Protein Breakdown Products : Protein Synthesis and Turn-over in Cultured Plant Tissue (Dr. R. G. S. Bidwell et *al.*), 367
Carbonate in a Low-density Fraction of Diaphyseal Bone : Presence of (Dr. L. Richelle and N. Quinaux), 84
Carbonic Anhydrase : A Variation in the Electrophoretic Pattern of Human Erythrocyte (Dr. R. F. Rieder and Dr. D. J. Weatherall), 1364
Carbonic Anhydrase in the Mamillæ of the Hen's Egg Shell (T. Diamantstein, Prof. K. Bronsch and J. Schlüns), 88
Carcinogenesis : Mechanisms of, 23
Carcinogenic Hydrocarbon of Incorporation of Tritiated Cytidine into Mouse Epidermal Cells : Inhibition by a (Dr. N. R. Sinclair and Prof. J. A. McCarter), 521
Carcinogens : Contact Reactivity to Azo Dye (Dr. J. Gordon), 884
Carcinogens by Lysosomes : Uptake of Hydrocarbon (Dr. A. C. Allison and Dr. L. Mallucci), 1024
Carcinoma by an Immunochromatographic Method : Preparation of Antigens Specific of Human Breast (Dr. S. DeCarvalho), 1186
Carcinoma Cells at High Ultra-centrifugal Forces : Survival of Ehrlich's Ascites (Dr. N. Molomut et *al.*), 740
Carcinomas of the Skin induced by Dimethylbenzanthracene (DMBA) in Mice of the Strain XVIII/*Bln* : Resistance against (G. Pasternak et *al.*), 307
Carcinus : Lability of the Action Potential and the Recovery Cycle from Isolated Motor Axons of the Crab (R. A. Chapman), 872
Carcinus maenas : Secondary Immune Response to Bacteriophage *T1* in the Shore Crab (A. E. Taylor et *al.*), 775
Cardinali, Dr. Giuliana, et *al.* : Effect of Colchicine on Human Tumours transplanted in Cheek Pouch of Syrian Hamster, 90
Cardinali, Dr. Giuseppe, et *al.* : Effect of Colchicine on Human Tumours transplanted in Cheek Pouch of Syrian Hamster, 90
Cardiotoxicity of Drugs : Influence of Psychological Stress on the Specific (Prof. A. Marino), 1289
Carey, J., and Warner, Dr. N. L. : Gamma-globulin Synthesis in Hormonally Bursectomized Chickens, 198
Carmack, C., et *al.* : Mechanisms of Inactivation of Single-stranded Virus Nucleic Acids by Heat, 606
Carnegie Institution Fellowship awarded to Dr. T. B. Mulholland, 1121
Caroselli, N. E., and Mahadevan, Prof. A. : Nature of Growth-promoting Activity associated with the Culture Filtrates of *Fusarium oxysporum f. lycopersici* (Sacc.) Snyd. and Hans, 665
β-Carotene : Current Pulses in (D. Chapman and R. J. Cherry), 641
β-Carotene against Lethal Photosensitization by Hæmatoporphyrin : Protective Effect of (Dr. M. M. Mathews), 1092
β-Carotene by Hydroperoxides : Oxidation of (Dr. M. Elahi and Prof. E. R. Cole), 186
Carotid Body : Cytochemical Demonstration of Catecholamines in the Human (Dr. M. Niemi and Dr. K. Ojala), 539
Carpenter, A., et *al.* : Falling Efficiency at Sorting Cards during Acclimatization at 19,000 ft., 436
Carr-Saunders, Sir Alexander : *Staffing African Universities*, 1314
Carriage of Dangerous Goods : International, 1015
Carrier-free (7-^{3}H)-Testosterone (Dr. M. M. Coombs and H. R. Roderick), 523
Carrot stored in Oxygen : Off-flavour of Dehydrated (J. E. Ayers et *al.*), 81
Carruthers, Dr. W. : Smoking and Health : Report of the Advisory Committee to the Surgeon-General of the Public Health Service, *review*, 221
Carswell, E. A., et *al.* : *ML* : A New Antigen found in Leukæmias and Mammary Tumours of the Mouse, 1033
Carter, G. A., and Spencer, Dr. D. M. : Antifungal Activity in Orange Tissue infected with *Aspergillus niger*, 894
Cartwright, J. : Distribution of Particle Size in Dust, 1057
Casa, D. D., and Burnell, R. H. : Quaternary Alkaloid from *Croton turumiquirensis*, Stayerm, 296
Case of an Inappropriate Model (Dr. M. Hammerton), 63
Catalytic Decomposition of Glucose in Aqueous Solution by Thermal Proteinoids (Prof. S. W. Fox and Dr. G. Krampitz), 1362
Catchpole, Prof. H. R., et *al.* : Chemical Potentials and Electrical Potentials in Biological Systems, 931
Catecholamines : Effects of Lumbar Sympathectomy on the Uterine uptake of (Dr. J. E. Fischer et *al.*), 938

Catecholamines in the Human Carotid Body : Cytochemical Demonstration of (Dr. M. Niemi and Dr. K. Ojala), 539
Cations : Increase of the Effectiveness of Polyene Antibiotics, with Univalent (Dr. I. Horváth and I. Koczka), 1305
Cattle : Chromosome Abnormality in Three Cases of Lymphatic Leukæmia in (I. Gustavsson and G. Rockborn), 990
Cattle as affected by Intake of Feed : Comparative Digestive Capacities of *Bos taurus* and *Bos indicus* (Dr. J. R. Howes and Prof. J. F. Hentges, jun.), 784
Cawthron, Thomas, and the Cawthron Institute (David Miller), *review* by Dr. G. W. Cooke, 802
Cell Culture Monolayers : Homotransplantation Antibodies detected by Mixed Agglutination with (C. J. Abeyounis et *al.*), 313
Cell Cycle in Lens Epithelium : Chromosome Duplication and the (Dr. B. D. Srinivasan), 100
Cell Division : Carbon Dioxide and (Dr. C. Sorokin), 1252
Cell Division in Tissue Cultures by Gibberellic Acid : Promotion of (J. Digby et *al.*), 547
Cell-free System : Initiation of Polypeptide Chains in the Reticulocyte (Dr. J. O. Bishop), 40
Cell Line with Phase of the Growth Cycle : Variations in Radiosensitivity of a Mammalian (H. Madoc-Jones), 983
Cell Membranes : Oligomycin and Active Transport Reactions in (Dr. R. Whittam et *al.*), 720
Cell Migration during Cortical Histogenesis : Pattern of (Dr. M. Berry et *al.*), 591
Cell and of the Cell Wall : Effects of Inositol-deficiency on Yeast with Particular reference to Chemical Composition of the (Dr. S. W. Challinor et *al.*), 250
Cells : Inhibitory Levels of Fluoride on Mammalian (Dr. J. A. Albright), 976
  Recovery following X-irradiation of Synchronized Chinese Hamster (Dr. W. K. Sinclair and R. A. Morton), 247
Cells by 5-Bromodeoxyuridine : Mechanisms of Sensitization to X-rays of Mammalian (Dr. J. T. Lett et *al.*), 593
Cells in Suspension Culture : Quantity Production of Synchronized Mammalian (D. F. Petersen and E. C. Anderson), 642
Cells in Tissue Culture : Phytohæmagglutinin-induced Cytotoxic Action of Normal Lymphoid Cells on (Dr. G. Holm et *al.*), 841
Cellular Component of Thymic Function (Dr. E. Leuchars, A. M. Cross, Dr. A. J. S. Davies and V. J. Wallis), 1189
Cellulase in Tomato Fruits (D. B. Dickinson and J. P. McCollum), 525
Cement, Blast-furnace, in South Africa (B. H. Milner), 1024
Cement Clinker and Water : Reaction between Portland (A. K. Chatterji and Phatak), 138
ω Centauri : Rotation of the Globular Cluster (Sir Richard Woolley), 961
Central Adaptation in Mechanisms of Form Vision (Prof. D. M. MacKay), 993
Central Nervous System of a Mollusc : Non-cholinergic Synaptic Inhibition in the (Dr. H. M. Gerschenfeld), 415
Central Nervous System Serotonin and Norepinephrine Localization in Emotional and Non-Emotional Strains in Mice (Dr. H. S. Sudak and Dr. J. W. Maas), 1254
Centrifugation : Effects of Deceleration on Rats exposed to Prolonged (Dr. J. Oyama and W. T. Platt), 766
Cercopithecus aethiops : Activities of Pseudocholinesterases (Acylcholine-Acylhydrolase *EC* 3.1.1.8) in *Macaca mulatta* (*rhesus*) and (Dr. H. W. Goedde and V. Riedel), 1405
Cerebellar Factor : Identity of the (Dr. J. Crossland, Dr. G. N. Woodruff and Dr. J. F. Mitchell), 1388
Cerebellar Purkinje Cells by the Climbing Fibres : Excitation of (Sir John Eccles, et *al.*), 245
Cerebral Arteries of Sheep : Localization of Spontaneous Lipid Deposition in the (Dr. W. E. Stehbens), 1294
Cerebral Cortex by Electrical Stimulation of the Uterus : Potentials evoked in the Hypothalamus and (Dr. V. C. Abrahams et *al.*), 654
Cerny, Dr. J., et *al.* : Inadequacy of Thermal Initiation Theory in Interpreting the Results of Fission Fragment Irradiation of Explosives at Elevated Temperatures, 473
Cerqua, R., et *al.* : Deoxycorticosterone Acetate and Experimental Atherosclerosis in Cholesterol-fed Rabbits, 252
Ceruloplasmins of the Pig : Inherited Variants in Serum (P. Imlah), 658
Cestoda and Acanthocephala in the Intestines of Freshwater Fish : Evidence for a Dynamic Equilibrium in the Incidence of (Dr. J. C. Chubb, Dr. J. B. E. Awachie and C. R. Kennedy), 986
Cetacea : Retino-hypothalamic Connexions in (Prof. M. S. Jacobs and Dr. P. J. Morgane), 778
Chadderton, L. T., et *al.* : Inadequacy of Thermal Initiation Theory in Interpreting the Results of Fission Fragment Irradiation of Explosives at Elevated Temperatures, 473
Chadderton, Dr. L. T., and Torrens, I. Mc.C. : Electron Microscope Observation of Nuclear Reactions, 387
Chain, Prof. E. B., et *al.* : Fusicoccin : a New Wilting Toxin produced by *Fusicoccum amygdali* Del, 297
Chakravarti, D., et *al.* : Analyses of Radionuclides of Biological Interest in Pacific Waters, 571
Challinor, Dr. S. W., et *al.* : Effects of Inositol-deficiency on Yeast with Particular Reference to Chemical Composition of the Cell and of the Cell Wall, 250
Chaloner, Dr. W. G. : Fundamentals of Palæontology, Vol. 15, *review*, 685
Chambaut, A. M., et *al.* : Biological Activity of Natural and Synthetic Insulin *A*-chain Preparations on the Isolated Rat Diaphragm, 408
Chamberlain, E., and Hoekstra, Dr. P. : Electro-osmosis in Frozen Soil, 1406
Chambers, S. P. : Education and Industry. Substance of the Chuter Ede Lecture delivered before the National Union of Teachers, 227
  Science and Mankind, 1010
Champness, D. L., et *al.* : Malaria Antibody Content of Gamma$_2$-7S Globulin in Tropical Populations, 1366
Chang, Dr. M. C., et *al.* : High Resistance of Mongolian Gerbils to Irradiation, 536
Chang, S. F., and Liener, Prof. I. E. : New Chromophoric Reagents for Labelling the Thiol Groups of Proteins, 1065
Changing Role of Science and Technology (Dr. J. A. Stratton). Substance of the ninety-eighth Commencement Address delivered at the Massachusetts Institute of Technology, 455
Channel Tunnel, 918
Chantry, Dr. G. W., et *al.* : Interferometric Raman Spectroscopy using Infra-red Excitation, 1052
Chapman, C. J., et *al.* : Further Uses of Electronically Scanned Sonar in the Investigation of Behaviour of Fish, 588
Chapman, D., and Cherry, R. J. : Current Pulses in β-Carotene, 641
Chapman, R. A. : Lability of the Action Potential and the Recovery Cycle from Isolated Motor Axons of the Crab, *Carcinus*, 872
Chapman, Dr. R. M., and Bragdon, H. R. : Evoked Resposes to Numerical and Non-numerical Visual Stimuli while Problem Solving, 1155
Chapman, V., and Riley, Dr. R. : Cytological Determination of the Homœology of Chromsomes of *Triticum aestivum*, 156
Chargaff, Prof. E., awarded the 1963 Charles Léopold Mayer Prize, 24
Chargaff, Prof. E., et *al.* : Rhythmic Alternations in the Rate of Synthesis and the Composition of Rapidly Labelled Ribonucleic Acid during the Synchronous Growth of Bacteria, 479
Charnock, H. : High Salinity in Sea Water, 590
Chatagner, Dr. F. : Occurrence of Homoserine in the Liver of Ethionine- or Methionine-treated Rats, 1177
Chatterjee, S., et *al.* : Structural Investigation of 4-[(-Amino-5-pyrimidinyl)-imino]-2-penten-2-ol., 970
Chatterji, A. K. : Semiconduction in Kaolin, 284
Chatterji, A. K., et *al.* : Thermionic Emission and Heat of Hydration of Lime, 61
Chatterji, A. K., and Phatak, T. C. : Reaction between Portland Cement Clinker and Water, 138
Cheek Pouch of Syrian Hamster : Effect of Colchicine on Human Tumours transplanted in (Dr. G. Cardinali et *al.*), 90
Cheesman, Dr. D. F. : Varro and the Small Beasts : A Bimillennium for Microbiologists, *review*, 911
Chelsea College of Science and Technology : Appointments, 578
Chemical Analysis of Soils (K. K. Gedroits), *review* by Dr. C. Bloomfield, 334
Chemical Bonding : Atomic Structure and (Fritz Seel), *review* by Dr. D. J. Millen, 114
Chemical Engineering Practice, Vol. 7 (edited by H. W. Cremer), *review* by Prof. J. M. Coulson, 681
Chemical Institute of Canada, symposium on "High Temperature Inorganic Chemistry", 128
Chemical Potentials and Electrical Potentials in Biological Systems (Dr. N. R. Joseph, Dr. M. B. Engel and Prof. H. R. Catchpole), 931
Chemical Protective Agents (Cysteamine and β-Aminoethylisothiuronium (AET) Cl HCl) and Homologous Testes-DNA on the Death-rate of the Progeny of a First Generation originating from Male Rats irradiated in the Infantile Period : Effect of (Dr. N. Savkovič), 1393
Chemical Protective Agents and Doses of X-irradiation : Quantitative Relations between Doses of (Prof. R. Koch and I. Seiter), 984
Chemical Technology : Encyclopedia of (Kirk-Othmer), Vol. 2, and Vol. 3, second revised edition, *review* by Dr. K. Field, 804, 1005
Chemical Toxicology : Progress in, Vol. 1 (edited by Abraham Stolman), *review* by Dr. H. V. Street, 562
Chemical Weathering on Parent Material : Effect of (P. Bayliss), 327
Chemically Specified Molecular Mechanism Underlying Excitation in Nerve : A Hypothesis (Prof. J. M. Tobias), 13
Chemi-luminescence as a Diagnostic Feature of Heterolytic Reactions which produce Oxygen (E. McKeown and Dr. W. A, Waters), 1063
Chemistry : Space and Time in (Prof. A. Maccoll), 809
Chemistry and Biochemistry of Fungi and Yeasts : Proceedings of the Symposium on the Chemistry and Biochemistry of Fungi and Yeasts, July 1963, *review* by C. Rainbow, 803
Chemotherapeutic Agents and those of X-rays on the Reproductive Capacity of Mammalian Cells : A Comparison of Effects of Some (Dr. R. J. Berry), 1150
Chemotherapy with Actinomycin *D* and Ribonuclease : an Example of Complementary Inhibition : Combination (Prof. A. C. Sartorelli), 877
Cherry, R. D. : Alpha-Radioactivity of Plankton, 139
Cherry, R. J., and Chapman, D. : Current Pulses in β-Carotene, 641
Chesters, Prof. C. G. C. : Fungal Friends and Foes, 953
Chiasma and Corpus Callosum in Monkeys : Optokinetic Nystagmus : An unlearned Response altered by Section of (Dr. T. Pasik and Dr. P. Pasik), 609
Chickens : Gamma-globulin Synthesis in Hormonally Bursectomized (J. Carey and Dr. N. L. Warner), 198
Childs, The Jane Coffin, Memorial Fund, 350
Chimæras : By Syngeneic Radiation (Dr. A. J. S. Davies et *al.*), 1039
  By Thymectomized Syngeneic Radiation (A. M. Cross et *al.*), 1042
Chin, M., et *al.* : Decomposition of Dilute Hydrogen Peroxide in Alkaline Solutions, 1281
Chinneck, A. : National Physical Laboratory, 579
Chivers, H. J. A., and Hargreaves, J. K. : Fluctuations in Ionospheric Absorption Events at Conjugate Stations, 963
Chlamydomonas reinhardii, A Single-gene Mutation of, Affecting Motility : A Genetic and Electron Microscope Study (Sir John Randall et *al.*), 912
Chlamydomonas snowiae by Indolyl-3-acetic Acid and Ethylene-diamine Tetra-acetic Acid : Induction of Phototaxis in (I. Chorin-Kirsh and Dr. A. M. Mayer), 1085
Chloralose : Actions and Dosage of (Dr. P. G. Croft), 1086
Chloramine T. : Efficient Labelling of Tissue-soluble Proteins with Iodine-131 using (Dr. V. Bocci), 985
Chloramphenicol as an Inhibotor of Energy-linked Processes in Maize Mitochondria (C. D. Stoner, Dr. T. K. Hodges and Prof. J. B. Hanson), 258
Chloramphenicol by Sensitive and Resistant Organisms : Uptake and Binding of (Dr. D. Vazquez), 257
Chloramphenicol and Tetracycline : Development *in vitro* of Bacterial Cross-resistance involving Pencillins (R. Sutherland et *al.*), 548
Chlorella pyrenoidosa : Influence of the Inoculum and the Medium on the Growth of (Dr. M. Rodriquez-López), 666
Chlorine Atoms : Recombination of (E. Hutton), 835
Chlorine-36 produced by Neutron Capture in Meteorites (Prof. P. S. Goel), 1162
Chlorobenzene and Bromobenzene : Capture of Low-energy Electrons in (Dr. J. E. Lovelock et *al.*), 1267
Chlorogenic Acid, Pure, not Allergenic in Atopy to Green Coffee: a Specific Protein Probably is involved (Dr. L. L. Layton, F. C. Greene, Dr. J. W. Corse and Dr. R. Panzani), 188
Chlorophyll by Electrolytic Reduction : Formation of Phase Test Intermediate of (R. Felton, G. M. Sherman and Prof. H. Linschitz), 637
Chlorophyll *a* and Chlorophyll *b* and their Possible Role in the Light Reactions of Photosynthesis : Isolation from Spinach Chloroplasts of Particles containing Different Proportions of (Dr. N. K. Boardman and Dr. J. M. Anderson), 166
Chloroplasts : Some Properties of Differentially Centrifuged Particulate Fractions from (J. A. Gross et *al.*), 1263
Chloroplasts of Spinach isolated by a Non-aqueous Technique : Nucleic Acid Content of (J. Biggins and R. B. Park), 425
Chloroquine-resistant Malaria Parasites (*Plasmodium berghei*, Vincke and Lips, 1948) : Pigment Formation and Nuclear Division in (Dr. W. Peters), 1290
Cholesterol-fed Rabbits : Deoxycorticosterone Acetate and Experimental Atherosclerosis in (Dr. G. B. Rossi et *al.*), 252
Cholinesterase in Horse Plasma : Multiple Forms of (Dr. Y. Oki, Prof. W. T. Oliver and Dr. H. S. Funnell), 605
Chondrites : Possible Correlation between Classifications and Potassium-Argon Ages of (K. Keil), 511
Chopra, Dr. K. P., and Hubert, L. F. : Kármán Vortex-Streets in Earth's Atmosphere, 1341
Chopra, S. L., and Blackwood, Prof. A. C. : Toxic Action of Hæmolytic *Escherichia coli* isolated from Pigs, 667

Commonwealth, Teachers for the—the British Contribution (M. Elphick and R. Manley), *Planning*, **30**, No. 482, 1313
Commonwealth Universities Yearbook 1964, *review*, 446
Comparative Endocrinology, Vol. 2 (edited by U.S. von Euler and H. Heller), *review* by Prof. I. Chester Jones, 1003
Comparative Role of Nitrate and Molecular Oxygen in the Dissimilation of Glucose (Prof. C. M. Gilmour, R. P. Bhatt and J. V. Mayeux), 55
Complete Slimmer (Prof. John Yudkin), *review* by P. D. Nuttall, 447
Complex: Soil-Plant-Animal- (Dr. T. G. Taylor), 924
Complexation in Analytical Chemistry (Anders Ringbom), *review* by Dr. J. R. Cooke, 559
Compound, A $C_{15}H_{22}O_4$, produced by the Fungus *Aspergillus fischeri* var. glaber (J. J. Ellis, Dr. F. H. Stodola, R. F. Vesonder and C. A. Glass), 1382
Comte, Memorial Lecture, The sixth Auguste, delivered by Prof. A. J. Ayer, 698
Concrete: Stress Concentration in (Prof. W. Wright and Dr. J. G. Byrne), 1374
Conductivity: Suggested Units for (R. E. Barker, jun.), 513
Conn, jun., Dr. R. B., et *al.*: Inconstancy of Renal Clearance Value with Changing Plasma Concentrations, 143
Connective Tissue Research: International Review of, Vol. 1 (edited by David A. Hall), *review*, 1320
Contact Phase of Blood Coagulation (H. L. Nossel), *review* by Prof. G. V. R. Born, 682
Contact Reactivity to Azo Dye Carcinogens (Dr. J. Gordon), 884
Containment of Plasma in a Magnetic Mirror, with Hexapole Stabilizing Fields (G. Francis, D. W. Mason and J. W. Hill), 623
Continental Drift: Preparation of Spherical Caps for Use on Terrestrial Globes in Investigations of Palæomagnetism and (Prof. J. Hospers), 397
Contingent Negative Variation: An Electric Sign of Sensorimotor Association and Expectancy in the Human Brain (Dr. W. Grey Walter, Dr. R. Cooper, V. J. Aldridge, W. C. McCallum and A. L. Winter), 380
Contribution of New Instruments to Progress in Chemistry (Sir Harry Melville), 949
Conway, H. G.: Engineers at the Cross-roads, 951
Cooke, Dr. G. W.: Thomas Cawthron and the Cawthron Institute, *review*, 802
Cooke, Dr. J. R.: Complexation in Analytical Chemistry, *review*, 559
Cooling Time of Silica Fibres (R. G. C. Arridge and K. Prior), 386
Coombs, Dr. M. M., and Roderick, H. R.: Carrier-free (7-^{3}H)-Testosterone, 523
Cooper, D., and Sharman, G. B.: Transferrin Variation in Kangaroos, 1094
Cooper, P. J.: Solubilities of Inorganic and Organic Compounds, Vol. 1, Part 2, *review*, 339
Cooper, Prof. J. R., and McIntosh, J. C.: Function of *N*-Acetyl Aspartic Acid in the Brain: Effects of Certain Drugs, 658
Cooper, Dr. R., et *al.*: Contingent Netative Variation: An Electric Sign of Sensorimotor Association and Expectancy in the Human Brain, 380
Copper: Biliary Excretion of Cæruloplasmin (Dr. P. Aisen et *al.*), 873
Corals as Fish Food: Deep Water (Dr. D. F. Squires), 663
Corbett, G. B.: *The Identification of British Mammals*, 919
  Mammals of the U.S.S.R. and Adjacent Countries, Vol. 6, *review*, 1212
Corbet, P. S.: Antogeny and Oviposition in Arctic Mosquitoes, 669
Cordoba, F., et *al.*: Low Molecular Weight γ-Globulins of Urine and Plasma and their Relation to $7S\gamma_2$-Globulin, 78
Cores from Bacterial Spores by Mechanical Breakage in Acidic Media: Release of (A. D. Hitchins and Dr. G. W. Gould), 895

Cornea *in vitro* : Carbon Dioxide Efflux from the Human (Prof. I. Fatt, et *al.*), 738
Corolla Chromosomes from Flower Buds : Quick Preparation of (Dr. G. Haskell and E. B. Paterson), 673
Coronal Magnetic Field : Spectral Evidence on the Origin of Type I Solar Radio Storms and the (J. P. Wild and A. Tlamicha), 1128
Coronary Arteries : Simultaneous Electromagnetic Measurement of Blood Flow in the Major (Prof. A. Kolin et *al.*), 148
Corpora Allata of Worker Honey-bees (*Apis mellifera* L.) : Secretory Activity in the (Dr. J. E. J. Habowsky and W. E. Beckel), 1090
Corpus Callosum in Monkeys : Optokinetic Nystagmus : an Unlearned Response Altered by Section of Chiasma and (Dr. T. Pasik and Dr. P. Pasik), 609
Corpus Cardiacum Extracts on Hæmolymph Trehalose of the Cockroach, *Periplaneta americana* : Effects of Brain and (Prof. C. L. Ralph and R. McCarthy), 1195
Correa, Dr. J. N., and Andrews, Dr. J. R. : Modification of the Radiation Effect on Ascitic Tumour Cells by Pharmacological Agents injected intravenously, 200
Corse, Dr. J. W., et *al.* : Pure Chlorogenic Acid not Allergenic in Atopy to Green Coffee : a Specific Protein Probably is involved, 188
Cortical Cells of Human Hair : Transfer of Melanin Granules from Melanocytes to the (Dr. J. A. Swift), 976
Cortical Electrical Activity : Effect of Snake Venom and Endotoxin on (Capt. J. A. Vick et *al.*), 1387
Cortical Histogenesis : Pattern of Cell Migration during (Dr. M. Berry, et *al.*), 591
Cortical Neurones and Voluntary Movements in Man : Reciprocal Activation and Inhibition of : Cortical Cell Activity and Muscle Movement (Dr. C.-L. Li and Dr. J. M. Tew, jun.), 264
Corticoid Synthesis by Quartered Adrenal Glands of Rats Deprived of Vitamin E. : Adrenal Glands in Vitamin E Deficiency : *in vitro* (Dr. A. E. Kitabchi), 650
Cortisone-induced Cleft Palate : Oligohydramnios and (Dr. J. W. S. Harris), 533
Cosmic Helium Abundance : The Mystery of the (Prof. F. Hoyle and Dr. R. J. Tayler), 1108
Cossins, Prof. E. A. : Formation and Metabolism of Lactic Acid during Germination of Pea Seedlings, 989
Cota, H. M., et *al.* : Decomposition of Dilute Hydrogen Peroxide in Alkaline Solutions, 1281
Coulson, Prof. J. M. : Chemical Engineering Practice, Vol. 7, *review*, 681
Council for the Preservation of Rural England. Annual report 1963–64, 1340
  Twenty-fifth national conference, 1228
Counting Techniques : High Sensitivity (D. E. Watt and D. Ramsden), *review* by Prof. W. E. Burcham, 5
Course of Lectures on the Theory of Sound (S. N. Rschevkin), *review* by Prof. E. J. Richards, 560
Coursey, D. G., and Eggins, Dr. H. O. W. : Thermophilic Fungi associated with Nigerian Oil Palm Produce, 1083
Cowan, Dr. S. T. : Selected Papers of Ernst Georg Pringsheim, *review*, 909
Cox, Dr. B. S. : The Process of Evolution, *review*, 1208
Crab : Absence of Bile Salts in the Gastric Juice of a (A. van den Oord et *al.*), 301
Crab, *Carcinus* : Lability of the Action Potential and the Recovery Cycle from Isolated Motor Axons of the (R. A. Chapman), 872
Crab *Carcinus maenas* : Secondary Immune Response to Bacteriophage *T1* in the Shore (A. E. Taylor et *al.*), 775
Crab, A. Hermit, New to Britain (Prof. L. A. Harvey), 99
Crab Nebula at 38 Mc/s. : Detection of Fine Structure in the (Dr. A. Hewish and S. E. Okoye), 171
Crab Nebula during a Lunar Occultation : Radio Observations of the (B. H. Andrew et *al.*), 171
Crane, F. L., et *al.* : Second Naphthoquinone in Spinach Chloroplasts, 524
Crayfish Muscle : Iontophoretic Application of Gamma-Aminobutyric Acid on (Prof. A. Takeuchi and N. Takeuchi), 1074
Creange, J. E., et *al.* : Stimulation of Steroid C-11 β-Hydroxylase Activity in Adrenal Homogenates by Cyclic 3′,5′-Adenosine Monophosphate, 759
Creatinine, Variations of Urinary, and its Correlation to Tryptamine Excretion in Schizophrenic Patients (Dr. H. H. Berlet et *al.*), 1198
Creativity : Searching for (R. Weatherall), 925
Creer, Dr. K. M. : Reconstruction of the Continents for the Upper Palæozoic from Palæomagnetic Data, 1115
Cremer, H. W. (edited by) : Chemical Engineering Practice, Vol. 7, *review* by Prof. J. M. Coulson, 681
Crime and the Social Structure (Dr. John Barron Mays), *review* by Prof. D. C. Marsh, 109
Crisley, Dr. F. D. : Antibacterial Interaction between Bromthymol Blue and Polymyxin *B.*, 211
Croft, Dr. P. G. : Actions and Dosage of Chloralose, 1086
Cronly-Dillon, Dr. J. R. : Units Sensitive to Direction of Movement in Goldfish Optic Tectum, 214
Cross, A. M., et *al.* : By Syngeneic Radiation Chimæras, 1039
  By Thymectomized Syngeneic Radiation Chimæras, 1039
  Cellular Component of Thymic Function, 1189
  Time of Action of the Thymus, 1239
Cross, Dr. M. J. : *obituary* by Prof. G. V. R. Born, 1013
Crosskey, R. W. : Tsetse Flies in Northern Nigeria, *review*, 686
Crossland, Dr. J., et *al.* : Identity of the Cerebellar Factor, 1388
Crosslinking of Fibrous Proteins by Formaldehyde (Dr. P. Mason and Dr. J. C. Griffith), 484
Croton turumiquirensis, Stayerm : A Quaternary Alkaloid from (R. H. Burnell and D. D. Casa), 296
Crozaz, G., et *al.* : Rate of Accumulation of Snow at the South Pole as Determined by Radioactive Measurements, 393
Crustacea, Isopoda, Occurrence of *Asellus*, in Esthwaite and Ullswater, English Lake District (Prof. H. P. Moon), 894
Crustacean, *Euphausia pacifica* : Moulting Frequency of a Deep-sea (Dr. R. Lasker), 96
Cryoglobulin Precipitate : High-potency Antihæmophilic Factor Concentrate prepared from (Dr. J. G. Pool et *al.*), 312
Cryptorchism in Australian Merino Sheep (C. H. S. Dolling and M. G. Brooker), 49
Crystal and Molecular Structure of 1,3-Dihydro-1-hydroxy-3-oxo-1,2-benziodoxole (Dr. E. Shefter and Dr. W. Wolf), 512
Crystallites : Thermal Expansion of Pyrolytic Graphite and its Variation due to Non-Alignment of the (R. H. Knibbs and I. B. Mason), 58
Crystals : Anistropy of Friction in (Dr. F. P. Bowden et *al.*), 27
Cubero, Dr. M., et *al.* : Unit Cell and Space Group of $Co(thiourea)_4(NO_3)_2$, 513
Cubital Fossæ : Extension of Mammary Glands to the Popliteal and (Dr. M. Hirata-Hibi), 1398
Culture : Yeast Mitogenic Factor Active in Human Peripheral Leucocytes in (E. Gandini and Prof. S. M. Gartler), 898
Culture Filtrates of *Fusarium oxysporum f. lycopersici* (Sacc.), Snyd. and Hans. : Nature of Growth-promoting Activity associated with the (Prof. A. Mahadevan and N. E. Caroselli), 665
Cultured Plant Tissue : Protein Synthesis and Turn-over in (Dr. R. G. S. Bidwell et *al.*), 367
Cupric Insulin : Electron Paramagnetic Resonance in Single Crystals of (Prof. A. S. Brill and Dr. J. H. Venable, jun.), 752
Current Pulses in β-Carotene (D. Chapman and R. J. Cherry), 641
Curtain, Dr. C. C. : Concentrating Protein Solutions, 1380
Curtain, Dr. C. C., et *al.* : Malaria Antibody Content of Gamma$_2$-7*S* Globulin in Tropical Populations, 1366
Curtis, Dr. D. R., and Ryall, R. W. : Nicotinic and Muscarinic Receptors of Renshaw Cells, 652
Curtis, G. J. : Graft Transmission of the Flowering Stimulus from a Wild *Beta* Species to a Line of Beet selected for Resistance to Bolting, 201
Cuttlefish : Receptors in the Sucker of (Prof. P. Graziadei), 384
Cuzzupoli, M., et *al.* : Failure to induce Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs, 416
Cyclic Patterns of Body Temperature in the Quail : Effect of Photoperiod on (A. E. Woodard and F. B. Mather), 422
Cyclic Sulphur Imides : Pentasulphur Triimides : Completion of a Class of (Dr. H. Heal and J. Kane), 971
Cystathionine and its Control in *Salmonella typhimurium* : Synthesis of (Dr. R. J. Rowbury), 977
Cysteamine and β-Aminoethylisothiuronium (AET) Cl HCl) and Homologous Testes-DNA on the Death-rate of the Progeny of a First Generation originating from Male Rats irradiated in the Infantile Period : Effect of Chemical Protective Agents (Dr. N. Savkovič), 1393
L-Cysteine as Inhibitor of Potassium Retention by Brain Slices (Dr. K. D. Neame), 1067
Cytidine into Mouse Epidermal Cells : Inhibition by a Carcinogenic Hydrocarbon of Incorporation of Tritiated (Dr. N. R. Sinclair and Prof. J. A. McCarter), 521
Cytochemical Demonstration of Catecholamines in the Human Carotid Body (Dr. M. Niemi and Dr. K. Ojala), 539
Cytochemical Investigations of Deoxyribonucleic Acid-mediated Control of Ribonucleoprotein Metabolism (Dr. R. Love, A. M. Clark and Dr. G. P. Studzinski), 1384
Cytochemical and Immunochemical Analysis at the Electron Microscopy Level : Obtaining Contrasting Antibodies by Use of Iodine (L. B. Mekler, S. M. Klimenko, G. E. Dobrezov, V. K. Naumova, Yu. P. Hoffman and Prof. V. M. Zhdanov), 717
Cytochrome c : Magnetic-optical Rotation Spectra of (Dr. V. E. Shashoua), 972
Cytological Determination of the Homœology of Chromosomes of *Triticum aestivum* (Dr. R. Riley and V. Chapman), 156
Cytology : Laser in (Prof. A. D. Booth et *al.*), 789
Cytology and Cytochemistry of Acute Leukæmias (G. F. J. Hayhoe, D. Quaglino and R. Doll), *review* by Dr. M. H. Salaman, 683
Cytoplasm Exudate from Cut Phloem (Dr. R. Thaine), 544
Cytoplasm of HeLa Cells treated with Puromycin : Nucleolus-like Inclusions in the (Dr. G. P. Studzinski), 883
Cytoplasmic Inheritance in Amœbæ : Nuclear Transfer Investigations (Dr. S. E. Hawkins), 95
Cytotoxic Action of Normal Lymphoid Cells on Cells in Tissue Culture . Phytohæmagglutinin-induced (Dr. G. Holm et *al.*), 841
Czechoslovakia Society of Arts and Sciences, second congress, 351

DDT : Ethological Changes in *Anopheles pseudopunctipennis* in Mexico after Prolonged Use of (Prof. A. Martinez-Palacios and Dr. J. de Zulueta), 940
DDT-hydroxylation in Resistance : Role of (A. Morello), 785
Dainton, Prof. F. S., et *al.* : Formation of Triplet States of Solutes in the Radiolysis of Organic Liquids, 1050
Dale, Dr. H. C. A. : Retroactive Interference in Short-term Memory, 1408
Daly, Dr. J. J., and Maier, L. : Molecular Structure of Phosphobenzene, 1167
Dancewicz, D., and Halpern, Dr. A. : Thermal Annealing of Tellurium resulting from Isomeric Transition in Solid Sodium Tellurate, 856
Daniels, Dr. D. G. H., and Martin, H. F. : Antioxidants in Oats : Light-induced Isomerization, 299
Danielsson, H., et *al.* : Absence of Bile Salts in the Gastric Juice of a Crab, 301
Danyluk, Prof. S. S., and Gore, E. S. : Proton Magnetic Relaxation Times of Aqueous Tetra Alkyl Ammonium Halide Solutions, 748
Darwinian Approach to Immunity (Sir MacFarlane Burnet), 451
Das Gupta, Dr. M. K., and Basu, D. : Slowly Varying Component of Solar Radio Emission in Relation to the Solar Cycle, 626
Dates : Handling, Processing and Packing, 460
Datt, Dr. N. S. : Hæmagglutination Reaction with Vaccinia Virus : Agglutinability of Red Cells from Turkeys, 1406
Datta, Dr. P., and Gest, Prof. H. : Alternative Patterns of End-Product Control in Biosynthesis of Amino-Acids of the Aspartic Family, 1259
Davidson, Prof. C. F. : Face of North America : The Natural History of a Continent, *review*, 5
Davidson, G., and Service, M. W. : A High Incidence of Dieldrin-resistance in *Anopheles gambiae* Giles from an Unsprayed Area in Northern Nigeria, 209
Davidson, J. N., and Cohn, W. E. (edited by) : Progress in Nucleic Acid Research, Vols. 1 and 2, *review* by Dr. S. Brenner, 1004
Davies, Dr. A. J. S., et *al.* : By Syngeneic Radiation Chimæras, 1039
  By Thymectomized Syngeneic Radiation Chimæras, 1039
  Cellular Component of Thymic Function, 1189
  Time of Action of the Thymus, 1239
Davies, Dr. C. N. : Inhaled Radioactive Particles and Gases, 352
  Surface Contamination, 463
Davies, D. K. : Trapped Charges on Dielectrics, 290

Electric Organ : Energetics of the (Dr. R. D. Keynes and Prof. X. Aubert), 261
Electric Sign of Sensorimotor Association and Expectancy in the Human Brain : Contingent Negative Variation : an (Dr. W. Grey Walter et *al.*), 380
Electric and Magnetic Field Problems : Analysis and Computation of (K. J. Binns and P. J. Lawrenson), *review* by E. M. Freeman, 225
Electrical Conduction in Amorphous Films (Dr. C. Feldman), 964
Electrical Conductivity of Anils : Effect of Substituents on (E. W. Gooden), 515
Electrical Engineers : Matrix Algebra for (R. Brace), *review* by Dr. W. J. Gibbs, 338
Electrical Insulation of the Division of Engineering and Industrial Research, National Academy of Sciences, annual meeting, 1124
Electrical Potentials in Biological Systems : Chemical Potentials and (Dr. N. R. Joseph et *al.*), 931
Electrical Research Association, open days, 1228
Electrical Resistance to Vigour of Apple Scions : Relation of (Prof. C. D Taper and R. S. Ling), 782
Electrical Resistivity of the Crust and Upper Mantle at Eskdalemuir, South Scotland (S. Jain), 631
Electrical Stimulation of the Uterus : Potentials evoked in the Hypothalamus and Cerebral Cortex by (Dr. V. C. Abrahams et *al.*), 654
Electrical and Mechanical Activity of Isolated Vascular Smooth Muscle of the Rat (Dr. S. Funaki and Prof. D. F. Bohr), 192
Electrical and Mechanical Activity of the Uterus in the Unanæsthetized Animal Simultaneous Recording of (Dr. P. Bass and M. R. Callantine), 1367
Electrically Charged Torque Pendulum (E. J. Saxl), 136
Electrodeposition from Acidic Solutions : Production of Gallium by Continuous (Dr. R. L. Sterans), 749
Electrodeposition Method for the Preparation of Electron Microscope Specimens (W. Parker and H. Baumgartner), 715
Electrolytic Reduction : Formation of Phase Test Intermediate of Chlorophyll by (R. Felton et *al.*), 637
Electromagnetic Waves from very Dense Stars (Prof. F. Hoyle, Dr. J. V. Narlikar and Prof. J. A. Wheeler), 914
Electromyographic Analysis of Laryngeal Articular Reflexes (Prof. J. A. Kirchner and Dr. B. Wyke), 1243
"Electron Emission", conference, 920
Electron Emitters : Porous (Dr. R. Dewsberry), 746
Electron Histochemical Examination of Oxidative Enzymes and Mitochondria (Dr. K. Ogawa and Prof. R. J. Barrnett), 724
Electron Microprobe Analysis of the Metallic Phase in Basic Achondrites (Dr. J. F. Lovering), 70
Electron Microscope Images : Graininess in the Photographic Recording of (Dr. R. C. Valentine and N. G. Wrigley), 713
Electron Microscope Observation of Nuclear Reactions (Dr. L. T. Chadderton and I. McC. Torrens), 387
Electron Microscope Observations on Mitotic Chromosomes in Erythroblasts of the Newt, *Triturus cristatus cristatus* (Dr. H. G. Davies and J. Tooze), 990
Electron Microscope Specimens : Electrodeposition Method for the Preparation of (W. Parker and H. Baumgartner), 715
Electron Microscope Study : A Single-gene Mutation of *Chlamydomonas reinhardii* affecting Motility : A Genetic and (Sir John Randall et *al.*), 912
Electron Microscopy : Atlas of (compiled by F. Scanga), *review* by Prof. R D Preston, 1103
  Embedding and Staining Small Nematodes for (Dr. A. F. Bird), 1300
"Electron Microscopy", third European regional conference, 24

Electron Microscopy Level : Cytochemical and Immunochemical Analysis at the : Obtaining Contrasting Antibodies by Use of Iodine (L. B. Mekler et *al.*), 717
Electron-oxidation Products using an Auxiliary Mercury Electrode : Determination of (Dr. P. Valenta and Dr. J. Koryta), 639
Electron Paramagnetic Resonance in Single Crystals of Cupric Insulin (Prof. A. S. Brill and Dr. J. H. Venable, jun.), 752
"Electron Probe X-ray Microanalysis", first European colloquium, 462
Electron Spin Resonance in Hæmin, Hæmatin and Hæmoglobin at 4·2° K (Dr. G. Schoffa), 640
Electron Spin Resonance Investigations of Ultra-violet and X-irradiated Bovine Serum Albumin (Prof. R. Koch and H. Mönig), 859
Electron Spin Resonance Spectra of $\alpha\alpha$-Diphenyl-β-picrylhydrazyl in Various Frozen Solvents : Effect of Micro-crystal Formation on the (Dr. P. B. Ayscough et *al.*), 1378
Electron Spin Resonance Spectra of γ-Irradiated Alkoxides (J. E. Bennett), 514
Electron and Vacuum Physics : Proceedings of the Symposium on, Hungary, 1962 (chief editor : Ernö Winter), *review* by J. Yarwood, 336
Electronic Effects and L-Amino-acid Oxidase Specificity (Dr. G. K. Radda), 936
Electronic Instrument for Estimation of Pasture Yield : An Improved (Dr. M. B. Alcock), 1309
Electronic Structures of Kryptates and Xenates (Dr. D. S. Urch), 403
Electronically Scanned Sonar in the Investigation of Behaviour of Fish : Further Uses of (Dr. V. G. Welsby, J. R. Dunn, C. J. Chapman, D. P. Sharman and R. Priestley), 588
Electrons, Capture of Low-energy, in Chlorobenzene and Bromobenzene (Dr. J. E. Lovelock et *al.*), 1267
Electrons in the Radiolysis of Propane : Nitrous Oxide as a Scavenger for (Dr. G. R. A. Johnson and J. M. Warman), 73
Electrons of Several MeV Energy : Lifetimes of Geomagnetically Trapped (J. A. Van Allen), 1006
Electro-osmosis in Frozen Soil (Dr. P. Hoekstra and E. Chamberlain), 1406
Electrophoresis : Fractionation of Trypsin by Paper (A. Iachan et *al.*), 43
Electrophoresis on 'Pevikon C-870' : Soluble Liver Proteins Fractionation by Zone (Dr. V. Bocci), 775
Electrophoretic Pattern of Human Erythrocyte Carbonic Anhydrase : Variation in the (Dr. R. F. Rieder and Dr. D. J. Weatherall), 1364
Electroretinogram : Duplex Function in the Grey Squirrel's (Dr. P. Gouras), 767
Eliasson, Prof. R. : Origin of Neuraminic Acid in Seminal Fluid, 980
Ellett, W. H., and Brownell, Dr. G. L. : Cæsium-137 Fall-out Body Burdens, Time Variation and Frequency Distribution, 53
Elliott, C. G., et *al.* : Steroid Growth Factor Requirement in a Fungus, 427
Elliott, E. V., et *al.* : By Syngeneic Radiation Chimæras, 1039
Ellis, Prof. G. R. A. : Anomalous Doppler Radiation and Very-low frequency Emissions, 1271
Ellis, J. J., et *al.* : $C_{15}H_{22}O_4$ Compound produced by the Fungus *Aspergillus fischeri* var. glaber, 1382
Ellman, P., et *al.* : Permeability Factor in Pollen Extracts Active in Non-sensitized Mice, 1390
Elphick, J. O., and Suggate, R. P. : Coal Ranks and Geothermal Gradients in High-volatile Bituminous Coalfields, 72
Elving, Philip J., and Kolthoff, I. M. (edited by) : Treatise on Analytical Chemistry, Part I, Vol. 4, *review* by J. Thomson, 447
Elwell Award papers for 1964, 819
Embedding and Staining Small Nematodes for Electron Microscopy (Dr. A. F. Bird), 1300
Embryo Fibroblasts : An Effect of Interferon on Uninfected Chick (Dr. J. A. Sonnabend), 496
Embryological Conference, the seventh International, 351
Embryonic Human Cells by Rous Sarcoma Virus : Transformation of (Dr. L. Zilber and V. Shevijaghyn), 194
Embryos : Influence of Extraneous Ribonucleic Acid on the Differentiation of Hæmatopoietic Tissue in Chick (P. Malpoix), 520
Embryos, Resistance of Fish, to Chronic Irradiation (V. M. Brown and W. L. Templeton), 1257
Emergence of Potato Blight, 1843–46 (P. M. Austin Bourke), 805
Emmelot, Dr. P., et *al.* : α-Glycerolphosphate Production by Rat Hepatomas, 77
Emotional and Non-Emotional Strains in Mice : Central Nervous System Serotonin and Norepinephrine Localization in (Dr. H. S. Sudak and Dr. J. W. Maas), 1254
Emperor Penguins at Cape Crozier (Dr. B. Stonehouse), 849
Empirical Level Rule for Spectroscopic Terms approximating to *LS*-Coupling (E. W. T. Richards and A. Ridgeley), 1277
Encyclopedia of Chemical Technology (Kirk-Othmer), Vols. 2 and 3, second revised edition, *review* by Dr. K. Field, 804 ; 1005
Endocrine Research : Techniques in (edited by Peter Eckstein and Francis Knowles). Proceedings of a NATO Advanced Study Institute, Birmingham, 1962), *review* by Dr. E. T. Bell, 112
Endocrinology, the second International Congress of, 351
Endometrium : Mast Cells and Hyaluronic Acid in the Bovine (Dr. I. N. Likar et *al.*), 730
Endotoxin on Cortical Electrical Activity : Effect of Snake Venom and (Capt. J. A. Vick et *al.*), 1387
Endotoxin with 6-Mercaptopurine : Suppression of Antibody to : Effect of Antigen Dose (Dr. M. Rubenstein and Dr. S. M. Wolff), 1390
Energy Transfer in Proteins (L. Augenstein and J. Nag-Chaudhuri), 1145
Engel, C. E. : Film and Television in the Work of the Universities, 1125
Engel, Dr. M. B., et *al.* : Chemical Potentials and Electrical Potentials in Biological Systems, 931
Energetics of the Electric Organ (Dr. R. D. Keynes and Prof. X. Aubert), 261
Energy Gap of β Silver Selenide (A. S. Epstein, S. M. Kulifay and R. I. Stearns), 856
Engineer Buyers Guide, 1964, 127
Engineers at the Cross-roads (H. G. Conway), 951
Ennor, Prof. A. H., et *al.* : Biosynthesis of L-Serine Ethanolamine Phosphodiester, 410
Enolase and Fluorophosphate (Sir Rudolph Peters, M. Shorthouse and L. R. Murray) (202, 1331) ; *erratum*, 24
Enstatite Achondrite Meteorites : Luminescence of (C. J. Derham et *al.*), 134
Enteropneust from the Atlantic : Another Giant (Dr. C. Burdon-Jones and J. A. Petersen), 97
Enthalpy of Binding of Aromatic Amines to Bovine Serum Albumin (M. R. V. Sahyun), 1045
Entwistle, P. F. : Mirids and Other Insect Pests of Cocoa, 922
Enumerating Viable Bacteria (Dr. W. Koch and Dr. D. Kaplan), 896
Environments : Responses of a New Hibernator (*Citellus variegatus*) to Controlled (E. T. Pengelley), 892
Enzootic Abortion of Ewes (M. J. Studdert and P. C. Kennedy), 1088
Enzymatic conversion of All-*cis*-Polyunsaturated Fatty Acids into Prostaglandins (D. A. van Dorp, R. K. Beerthuis, D. H. Nugteren and H. Vonkeman), 839
Enzymatic Mechanisms : Isotopic Exchange at Equilibrium as a Criterion of (Dr. J. Tze-fei Wong and Prof. G. S. Hanes), 492
Enzyme : Variety of Substrates for a Bacterial Benzyl Penicillin-splitting (Dr. W. Kaufmann and K. Bauer), 520
Enzyme Activation in Germinating *Petunia* Pollen (R. G. Stanley and H. F. Linskens), 542
Enzyme Forms : Nomenclature of Multiple (Dr. E. C. Webb), 821
Enzyme from Soy-flour : Effect of *N*-Ethylmaleimide on the Starch-liquefying (Y. Pomeranz and F. P. Mamaril), 863
Enzymes, Oxidative and Mitochondria : Electron Histochemical Examination of (Dr. K. Ogawa and Prof. R. J. Barrnett), 724
Ephrussi, Dr. B., et *al.* : Expression of Polyoma-induced Cellular Antigen(s) in Hybrid Cells, 495
Epidermal Cells : Inhibition by a Carcinogenic Hydrocarbon of Incorporation of Tritiated Cytidine into Mouse (Dr. N. R. Sinclair and Prof. J. A. McCarter), 521
Epididymis and Testis of the Sheep and Rat : Variations in Flow of Blood within the (Dr. B. P. Setchell et *al.*), 317
Epinephrine Control of Fatty Acid Release from Adipose Tissue : Effect of Aminonucleoside and Puromycin on Insulin and (Dr. A. Korner and Dr. M. S. Raben), 1287
Epinephrine within the Human Red Blood Cell : Interaction of Glutathione and (Dr. S. Roston), 1075
Epithelium : Chromosome Duplication and the Cell Cycle in Lens (Dr. B. D. Srinivasan), 100
Epithelial Cells from the Rodent Gastrointestinal Tract : Removal and Dissociation of (D. S. Harrer et *al.*), 319
Epstein, A. S., et *al.* : Energy Gap of β Silver Selenide, 856
Epstein, Dr. C. J. : Relation of Protein Evolution to Tertiary Structure, 1350
Epstein, W., et *al.* : Direct Demonstration of Reagin Activity in Purified γ_{1A}-Globulin, 1046
Equal Spheres : Pendular Moisture in Packings of (Prof. C. C. Harris and Dr. N. R. Morrow), 706
Erdman, Dr. J. G., and Stephan, R. : Detection of Divalent Sulphur Compounds on Paper and Thin-layer Chromatograms, 749
Erhlich, P. R., and Holm, R. W. : Process of Evolution, *review* by Dr. B. S. Cox, 1208
Erlanger, B. F., et *al.* : Fusicoccin : a New Wilting Toxin produced by *Fusicoccum amygdali* Del, 297
  Purine- and Pyrimidine-specific Antibodies : Precipitation with Denatured Deoxyribonucleic Acid, 1381
Erythroblasts of the Newt, *Triturus cristatus cristatus* : Electron Microscope Observations on Mitotic Chromosomes in (Dr. H. G. Davies and J. Tooze), 990
Erythrocyte Carbonic Anhydrase : Variation in the Electrophoretic Pattern of Human (Dr. R. F. Rieder and Dr. D. J. Weatherall), 1364
Erythrocytes : Conditions affecting the Glucose-6-phosphate Dehydrogenase Activity and Glutathione Stability of Human (Dr. J. P. H. Davies and Dr. D. B. Gower), 310
  Dissociation of Bacterial 0 Antigen from Rabbit (Prof. C. N. Shumway), 1081
  Effect of Hydrocortisone Hemi-succinate on Immune Lysis of Sheep (J. F. Jennings and Dr. G. Taylor), 661
  Effects of Tannic Acid and Mercury on Human (B. Ospina et *al.*), 788
Erythrocytes coated with 6-Aminopenicillanic Acid : Hæmagglutination of (Dr. K. C. Watson), 412
Erythrocytes coupled with Diazotized *p*-Nitroaniline : Panagglutination of (I. Wolff et *al.*), 1076
Escherichia coli : Properties of the Penicillin Deacylase Enzyme of (M. Cole), 519
  Segregation of Radiation-induced Mutations in (Dr. R. J. Munson and Dr. B. A. Bridges), 270
Escherichia coli isolated from Pigs : Toxic Action of Hæmolytic (S. L. Chopra and Prof. A. C. Blackwood), 667
Escherichia coli and *Drosophila* : Ethylation versus Methylation in Mutation of (Dr. T. Alderson), 1404
Eskdalemuir Bulletin, 127
Esposito, Prof. S. : Effect on Leukæmic Cells of Ribonucleic Acid extracted from Calf's Spleen, 1078
Essen, Dr. L. : Bearing of Recent Experiments on the Special and General Theories of Relativity, 395
Etch Pits on Calcite using Optically Active Etchants : Production of Dislocation (Dr. J. M. Thomas et *al.*), 72
Ethanol Consumption in Mice : Alcohol Dehydrogenase Activity and Previous (Prof. G. E. McClearn et *al.*), 793
Ethionine on Ribonucleic Acid Synthesis : An Anomalous Effect of (M. K. Turner and E. Reid), 1174
Ethionine- or Methionine-treated Rats : Occurrence of Homoserine in the Liver of (Dr. F. Chatagner), 1177
Ethological Changes in *Anopheles pseudopunctipennis* in Mexico after Prolonged Use of DDT (Prof. A. Martinez-Palacios and Dr. J. de Zulueta), 940
Ethylation versus Methylation in Mutation of *Escherichia coli* and *Drosophila* (Dr. T. Alderson), 1404
Ethylene : Biosynthesis of (Dr. S. P. Burg and E. A. Burg), 869
Ethylene-diamine Tetraacetic Acid : Induction of Phototaxis in *Chlamydomonas snowiae* by Indolyl-3-acetic Acid and (I. Chorin-Kirsh and Dr. A. M. Mayer), 1085
N-Ethylmaleimide on the Starch-liquefying Enzyme from Soy-flour : Effect of (Y. Pomeranz and F. P. Mamaril), 863
Euphausia pacifica : Moulting Frequency of a Deep-sea Crustacean (Dr. R. Lasker), 96
European Federation of Chemical Engineering, Third European Symposium, 462
Evans, C. R., et *al.* : Perception of Pattern and Colour in the Stabilized Retinal Image, 1200
Evans, D. E., et *al.* : Observation of Thomson and Co-operative Scattering of Ruby Laser Light by a Plasma, 1321
Evans, E. V., and Kenney, Dr. C. N. : Flow Method for Determining the Thermal Conductivity of Gas Mixtures, 184
Evans, Dr. H. E., et *al.* : Effect of Micro-crystal Formation on the Electron Spin Resonance Spectra of $\alpha\alpha$-Diphenyl-β-picrylhydrazyl in Various Frozen Solvents, 1378
Eveleigh, J. W., et *al.* : Amino-acid Sequence around the Reactive Thiol Groups of Adenosine Triphosphate-creatine Phosphotransferase, 267
Evoked Responses to Numerical and Non-numerical Visual Stimuli While Problem Solving (Dr. R. M. Chapman and H. R. Bragdon), 1155
Evolution : Science and Human (Dr. B. G. Campbell), 448
  The Process of (P. R. Erhlich and R. W. Holm), *review* by Dr. B. S. Cox, 1208
Evolution and Prevention of Drug-resistance (Prof. M. G. Sevag and B. Ashton), 1323
Ewen, A. H. : Knight of the White Eagle : A Biography of Sir Benjamin Thompson, Count Rumford (1753–1814), *review*, 3

Ewes : Enzootic Abortion of (M. J. Studdert and P. C. Kennedy), 1088
  Inhibitory Effect of Lactation on the Breeding Activity of the (J. L. Lees), 1089
  Transfer of Oxytocin from the Maternal to the Fœtal Circulation in the (Miss B. A. Noddle), 414
Exchange Labelling of 'Lipiodol' Ultra Fluids with Iodine-131 and its Intra-lymphatic Administration with a Fistula on the Thoracic Duct (J. Liebster and V. Kočandrle), 777
Excimers : Fluorescence of Organic Mixed (Dr. B. K. Selinger), 1062 ; (Dr. J. B. Birks), 1062
Excitation in Nerve : A Chemically Specified Molecular Mechanism Underlying : A Hypothesis (Prof. J. M. Tobias), 13
Excitation of Cerebellar Purkinje Cells by the Climbing Fibres (Sir John Eccles, R. Llinas and K. Sasaki), 245
Excitation of Primary Muscle Spindle Endings by β-Axon Stimulation (Dr. G. L. Kidd), 1248
Excreta of the Boll Weevil : Guanine in the (N. Mitlin and D. H. Vicker), 1403
Exercise of Mating Preference by a Merino Ram (R. H. Hayman), 160
Explosives at Elevated Temperatures : Inadequacy of Thermal Initiation Theory in Interpreting the Results of Fission Fragment Irradiation of (Lt. J. F. Mallay *et al.*), 473 ; (T. Boddington *et al.*), 473
Extraction of Uranium from Sea Water (R. V. Davies, Dr. J. Kennedy, R. W. McIlroy, Dr. R. Spence and K. M. Hill), 1110
Extraction and Purification of Calcitonin (Dr. A. Baghdiantz, Dr. G. V. Foster, A. Edwards, Dr. M. A. Kumar, Miss E. Slack, Dr. H. A. Soliman and Dr. I. MacIntyre), 1027
Extracts of Mould-infected Groundnut Samples in Tissue Culture (S. Juhász and E. Gréczi), 861
Eysenck, Prof. H. J. : Biological Basis of Criminal Behaviour, 952

F_2 REGION : Combined Effects of Drift and Diffusion in the (Dr. P. C. Kendall and Dr. D. W. Windle), 287
Fabian Society : *The Administrators* : *The Reform of the Civil Service*, 555
Face of North America : The Natural History of a Continent (Peter Farb), *review* by Prof. C. F. Davidson, 5.
Factor required for Growth Initiation of *Pasteurella tularensis* (Prof. J. Mager), 898
Fagerhol, Dr. M. K., *et al.* : Lack of Anti-A Hæmagglutinin Response to Influenza Infection, 1185
Failure to induce Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs (Dr. G. B. Rossi, P. Oriente, M. Cuzzupoli, A. Vecchione and M. Mancini), 416
Falling Efficiency at Sorting Cards during Acclimatization at 19,000 ft. (M. B. Gill, E. C. Poulton, A. Carpenter, M. M. Woodhead and M. H. P. Gregory), 436
Fall-out in London Rain Water (Dr. R. Wood, P. Metson and L. A. Richards), 617
Fall-out Strontium-90 in Deciduous Incisors and Fœtal Bone : Incorporation of (Dr. H. L. Rosenthal *et al.*), 615
Fankuchen, Prof. Isadore : *obituary* by Prof. J. D. Bernal, 916
Fantes, Dr. K. H., and O'Neill, C. F. : Some Similarities between a Viral Inhibitor of Plant Origin and Chick Interferon, 1048
Faraday Society, informal discussion on "The Electrical Double Layer in Surface and Colloid Chemistry", 462
Farb, Peter : Face of North America : The Natural History of a Continent, *review* by Prof. C. F. Davidson, 5
Farber, Prof. E., *et al.* : Biochemical Pathology of Acute Hepatic Adenosinetriphosphate Deficiency (substance of the Christian Herter Lecture, 1963), 34
Farradane, J. : Science Information, 820
Fat, Subcutaneous, of the Southern Elephant Seal : Insulating Capacity of the (M. M. Bryden), 1299
Fatt, Prof. I., *et al.* : Carbon Dioxide Efflux from the Human Cornea *in vivo*, 738
Fatty Acid Composition of Sebum associated with High Carbohydrate Diets : Changes in the (Dr. I. Macdonald), 1067
Fatty Acid Release from Adipose Tissue : Effect of Aminonucleoside and Puromycin on Insulin and Epinephrine Control of (Dr. A. Korner and Dr. M. S. Raben), 1287
Fatty Acids into Prostaglandins : Enzymatic Conversion of All-*cis*-Polyunsaturated (D. A. van Dorp *et al.*), 839
Fatty Metaplasia of the Filum Terminale of the Frog (Prof. R. L. Friede), 90
Faulkner, Dr. B. M., and Bull, Dr. A. T. : Physiological and Genetic Effects of 8-Azaguanine on *Aspergillus nidulans*, 506
Faulkner, J. K., and Woodcock, Dr. D. : Metabolism of 2,4-Dichlorophenoxyacetic Acid ('2,4-D') by *Aspergillus niger* van Tiegh, 865
Feed : Comparative Digestive Capacities of *Bos taurus* and *Bos indicus* Cattle as affected by Intake of (Dr. J. R. Howes and Prof. J. F. Hentges, jun.), 784
Feed-back Mechanism : Instability of Temperature Ice-sheets owing to a (L. Lliboutry), 627
Feeding of Vitamin C to Tomato Stems and Leaves (Prof. P. Hagene and J. Trichet), 783
Feldman, Dr. C. : Electrical Conduction in Amorphous Films, 964
Felton, R., *et al.* : Formation of Phase Test Intermediate of Chlorophyll by Electrolytic Reduction, 637

Guanine on Hepatic Glucose Release and on the Action of Insulin on the Liver : Effects of Adenine and (A. Kaldor *et al.*), 1186
Guanylic Acid—Inosinic Acid Pyrophosphorylase Deficiency in Mouse Fibroblasts : Three Degrees of (Dr. J. W. Littlefield), 1142
Guggenheim, The Daniel and Florence, International Astronautics Award for 1964 conferred on Prof. W. O. Fenn, 816
Guinness Awards for Science Teachers in Training (*Science Teacher*, **7**, No. 7), 823
Gulland Laboratory : Arthur D. Little, Ltd., 584
Gundermann, E. J., *et al.* : OH Absorption Spectra in Sagittarius, 65
Gupta, Mrs. S. Das, *et al.* : National Laboratories in India, 582
Gupta, D., and Tanner, Dr. J. M. : Steroid found in the Urine of Children but not Adults : A New, 187
Gurvich, A. E., and Drizlikh, G. I. : Use of Antibodies on an Insoluble Support for Specific Detection of Radioactive Antigens, 648
Gustafson, P. F., *et al.* : Concentrations of Cæsium-137, Rhodium-102 and Manganese-54 in Surface Air, 470
Gustavsson, I., and Rockborn, G. : Chromosome Abnormality in Three Cases of Lymphatic Leukæmia in Cattle, 990
Gustavsson, S. : Research into Research, 26
Guthrie, Prof. A. : Vacuum Technology, *review* by J. Yarwood, 682
Gutman, Dr. J., and Beyth, Dr. J. : Mechanism of Reversal of the Vasomotor Effect of Isoprenaline, 1291
Guttmann, R. D., *et al.* : Rejection of Isogeneic Murine Skin Grafts following Exposure to Allogeneic Ribonucleic Acid, 196
Gwyn, Dr. D. G., and Aitken, Dr. J. T. : New Motor End-plates and their Relationship to Muscle Fibre Injury, 651
Gynodiœcy in New Zealand *Genetiana* (C. J. Burrows and J. F. Hobbs), 203 ; (Dr. R. Melville), 203
György, Prof. P., *et al.* : Antioxidants isolated from Fermented Soybeans (Tempeh), 870

H CHAIN Groups of 7*S* γ-Globulin and the Gm System : A Relationship between the (Dr. H. G. Kunkel *et al.*), 413
Habits : Formation of Higher (Dr. J. A. Leonard and Dr. R. C. Newman), 550
Habowsky, Dr. J. E. J., and Beckel, W. E. : Secretory Activity in the Corpora Allata of Worker Honey-bees (*Apis mellifera* L.), 1090
Hæmagglutination of Erythrocytes coated with 6-Aminopenicillanic Acid (Dr. K. C. Watson), 412
Hæmagglutination Reaction with Vaccinia Virus : Agglutinability of Red Cells from Turkeys (Dr. N. S. Datt), 1406
Hæmatin and Hæmoglobin at 4·2° K : Electron Spin Resonance in Hæmin (Dr. G. Schoffa), 640
Hæmatopoietic Tissue in Chick Embryos : Influence of Extraneous Ribonucleic Acid on the Differentiation of (P. Malpoix), 520
Hæmatoporphyrin : Protective Effects of β-Carotene against Lethal Photosensitization by (Dr. M. M. Mathews), 1092
Hæmin, Hæmatin and Hæmoglobin at 4·2° K : Electron Spin Resonance in (Dr. G. Schoffa), 640
Hæmin Supplementation on Porphyrin Accumulation and Catalase Synthesis during Anaerobic Growth of *Staphylococcus* : Effect of (Dr. R. E. Heady, Dr. N. J. Jacobs and Dr. R. H. Deibel), 1285
Hæmoglobin : Interaction of Mercuric Ion with (R. A. Resnik), 880
    Structure of (Dr. M. F. Perutz *et al.*), 687
Hæmoglobin Gaccra (Dr. H. Lehmann, D. Beale and F. S. Boi-Doku), 363
Hæmoglobin at 4·2° K : Electron Spin Resonance in Hæmin, Hæmatin and (Dr. G. Schoffa), 640
Hæmolymph Trehalose of the Cockroach, *Periplaneta americana* : Effects of Brain and Corpus Cardiacum Extracts on (Prof. C. L. Ralph and R. McCarthy), 1195
Hæmolytic *Escherichia coli* isolated from Pigs : Toxic Action of (S. L. Chopra and Prof. A. C. Blackwood), 667
Hagene, Prof. P., and Trichet, J. : Feeding of Vitamin C to Tomato Stems and Leaves, 783
Hair : Transfer of Melanin Granules from Melanocytes to the Cortical Cells of Human (Dr. J. A. Swift), 976
Half-century of Fruit Research (Dr. J. Grainger), 822
Hall, David A. (edited by) : International Review of Connective Tissue Research, *review*, 1320

Hydrocarbon Liquids by Flow under Pressure through Porous Membranes : Separation of (Dr. S. Sourirajan), 1348
Hydrocarbons from Gaseous Methane in Low-frequency Electric Discharges : Differences in the Character of C_6 to C_9 (Dr. C. Ponnamperuma and F. Woeller), 272
Hydrocortisone : Maturation and Egg-laying of the Rabbit Flea (*Spilopsyllus cuniculi* Dale) induced by the External Application of (The Hon. Miriam Rothschild and B. Ford), 210
Hydrocortisone Hemi-succinate on Immune Lysis of Sheep Erythrocytes : Effect of (J. F. Jennings and Dr. G. Taylor), 661
Hydrocortisone on the Increase in Blood Glucose after Adrenaline : Rapid Action of (T. D. R. Hockaday), 1242
Hydrogen Compounds on Venus : Stability of (Dr. R. F. Mueller), 625
Hydrogen Peroxide in Alkaline Solutions : Decomposition of Dilute (H. M. Cota, T. Katan, M. Chin and F. J. Schoenweis), 1281
Hydrogen Singing-flame Ionization Detector (L. B. Graiff), 856
Hydrogen Sulphide on *Bullia* (Gastropoda) : Effect of (A. C. Brown), 205
Hydroperoxides : Oxidation of β-Carotene by (Dr. M. Elahi and Prof. E. R. Cole), 186
Hydrophobic Surface : Ice Nucleation and Growth in Supercooled Water Films condensed on a (Dr. H. M. Papée, *et al.*), 1343
2-(α-Hydroxybenzyl)-benzimidazole : Protection of Poliovirus-infected Tissue-culture Cells using the 1-Benzyl, 1-Pentyl and 1-Isopropyl Derivatives of (Dr. D. G. O'Sullivan *et al.*), 433
β-Hydroxybutyrate : Effect of Glucose on Insulin Secretion *in vitro* by Rabbit Pancreas pre-incubated with (J. Rojas *et al.*), 758
"Hydroxycinnamic Acids and Related Compounds", symposium on, 578
6β-Hydroxycortisol and 6β-Hydroxycortisone in Liquor Amnii : Isolation and Identification of the 20β-Hydroxy Derivatives of (M. Lambert and Prof. G. W. Pennington), 656
6β-Hydroxycortisone in Liquor Amnii : Isolation and Identification of the 20β-Hydroxy Derivatives of 6β-Hydroxycortisol and (M. Lambert and Prof. G. W. Pennington), 656
20β-Hydroxy Derivatives of 6β-Hydroxycortisol and 6β-Hydroxycortisone in Liquor Amnii : Isolation and Identification of the (M. Lambert and Prof. G. W. Pennington), 656
Hydroxyl Ions in the Mass Spectrum of Water Vapour (B. C. De Souza and Prof. J. H. Green), 1165
5-Hydroxytryptamine by Isolated Blood Platelets : Formation of 5-Hydroxytryptophol from Endogenous (G. Bartholini *et al.*), 1281
5-Hydroxytryptophan Decarboxylase in the Rat Pineal Gland : Neural and Photic Regulation of (Dr. S. H. Snyder *et al.*), 981
5-Hydroxytryptophol from Endogenous 5-Hydroxytryptamine by Isolated Blood Platelets : Formation of (G. Bartholini, Prof. A. Pletscher and H. Bruderer), 1281
Hyman, Herbert H. (edited by) : Noble Gas Compounds, *review* by Prof. J. S. Anderson, 442
Hyperbilirubinæmia in Full-term New-born Infants following Administration of Pregnane-3(alpha), 20(beta)-diol : Production of Unconjugated (Dr. I. M. Arias and Dr. L. M. Gartner), 1292
Hyperlipæmic Guinea Pigs : Failure to induce Atherosclerosis in 'Triton' (Dr. G. B. Rossi *et al.*), 416
Hyperpolarization : Ionic Changes Responsible for Post-tetanic (Dr. P. W. Gage and Dr. J. I. Hubbard), 653
Hyperpolarizing Action Potentials recorded from the Oesophagus of *Ascaris lumbricoides* (Prof. J. Del Castillo, W. C. de Mello and T. Morales), 530
Hyperthermia : A Thermoelectric Device for Inducing Local Tissue Hypothermia and (Dr. D. M. Makow and Dr. H. C. Grice), 613
Hypomyces Stage of *Fusarium solani f. pisi* (R. E. Reichle, Prof. W. C. Snyder and T. Matuo), 664
Hyponitrous Acid and Glucose Oxime : Mutagenic Action of (Prof. K. Yamafuji and Dr. K. Watanabe), 409
Hypothalamus and Cerebral Cortex by Electrical Stimulation of the Uterus : Potentials evoked in the (Dr. V. C. Abrahams, Dr. E. P. Langworth and Dr. G. W. Theobald), 654
Hypothermia and Hyperthermia : Thermoelectric Device for Inducing Local Tissue (Dr. D. M. Makow and Dr. H. C. Grice), 613
Hypoxia on the Rabbit during Exposure to Cold Effects of (Dr. B. Broom), 498

IACHAN, A., *et al.* : Fractionation of Trypsin by Paper Electrophoresis, 43
Iben, jun., Dr. I. : Gravitational Collapse, 1202
Ibsen, Dr. K. H., and Urist, Dr. M. R. : Relationship between Pyrophosphate Content and Oxytetracycline Labelling of Bone Salt, 761
Ibukun, Dr. O. : Lightning Flash Counts and Radio Noise Fields in the Tropics, 66
Ice Nucleation and Growth in Supercooled Water Films Condensed on a Hydrophobic Surface (Dr. H. M. Papée, Dr. A. C. Montefinale and Dr. T. W. Zawidzki), 1343
Ice Sheets owing to a Feed-back Mechanism : Instability of Temperature (L. Lliboutry), 627
Identification of the Bacteriostatic Component of 'Scotch' Brand of Cellulose Adhesive Tape (J. W. May and R. H. Houghton), 100
Igarashi, R. T., and Doi, Prof. R. H. : Relation of Ribonucleic Acid Composition to Growth Rate and Dormancy in *Bacillus subtilis*, 1092
Ikawa, T., *et al.* : Specificities of Several Acid Phosphatases from Plant Sources, 939
Ikehata, Dr. H., *et al.* : Antioxidants isolated from Fermented Soybeans (Tempeh), 870
Imaizumi, Prof. R., *et al.* : Mechanism of the Antihypertensive Effect of α-Methyldopa, 982
Imidazoleacetic Acid Riboside and Ribotide in Rat Tissues : Presence of (Dr. J. D. Robinson and Dr. J. P. Green), 1178
Imlah, P. : Inherited Variants in Serum Ceruloplasmins of the Pig, 658
Immune Lysis of Sheep Erythrocytes : Effect of Hydrocortisone Hemi-succinate on (J. F. Jennings and Dr. G. Taylor), 661
Immune Rabbit 7S Antibody and its Sub-units : Combination with Red Cells of (Dr. C. L. Greenbury *et al.*), 1147
Immune Response to Bacteriophage *T1* in the Shore Crab *Carcinus maenas* : Secondary (A. E. Taylor, Dr. G. Taylor and Prof. P. Collard), 775
Immunity : a Darwinian Approach to (Sir MacFarlane Burnet), 451
Immunochemistry, 1, No. 1 ; April 1964, 127
Immunochromatographic Method : Preparation of Antigens Specific of Human Breast Carcinoma by an (Dr. S. Decarvalho), 1186
Immuno-clinical Classification of *Staphylococcus pyogenes aureus* (Prof. H. Seneca and P. Peer), 787
Immunofluorescence in *NZB/NZW* Mice : Renal (I. Aarons), 1080
Immunofluorescent Detection of Proliferating Human Antibody-forming Cells (P. Urso and Dr. N. Gengozian), 1391
Immunological Control of Fertility in Female Mice (Dr. R. G. Edwards), 50
Immunological Distinction of *AKR* Thymocytes (Prof. A. E. Reif and Mrs. J. M. V. Allen), 886
Immunological Information : Retention of (by Staff of the Chester Beatty Research Institute), 1039
Immunological Paralysis induced in Adult Rabbits by Small Amounts of a Protein Antigen (Dr. D. W. Dresser and Dr. G. Gowland), 733
Inch Conversion : Metric to (W. M. Anderson and B. E. Robinson), 551
Incidence and Possible Significance of Inhaled or Ingested Polonium (Sir Ernest Marsden), 230
Inconstancy of Renal Clearance Values with Changing Plasma Concentrations (Dr. R. B. Conn, jun., A. J. Sabo, D. Landes and J. Y. L. Ho), 143
Index : A Probabilistic Similarity (Dr. D. W. Goodall), 1098
Indolyl-3-acetic Acid and Ethylene-diamine Tetraacetic Acid : Induction of Phototaxis in *Chlamydomonas snowiae* by (I. Chorin-Kirsh and Dr. A. M. Mayer), 1085
Industrial Design, 823
Industrial Development in Britain : Traffic Problems and, 219
Industrial Research Laboratory : Function of an (Dr. J. Grant), 467
Industrial Training Boards, 1335
Industry : Research Expenditure and (Prof. F. C. Thompson), 466
Infant and Neo-natal Mortality, 817
Infection of Wheat Roots by Ascospores of *Ophiobolus graminis* (D. H. Brooks), 203
Inflammation : Origin of Plasma Cells in Sites of (Prof. R. D. Moore and M. D. Schoenberg), 1293
Inflammatory Response of the Rat : Appearance of Slow α_2-Globulin during the (Prof. W. G. Heim and P. H. Lane), 1077
Influenza Infection : Lack of Anti-A Hæmagglutinin Response to (Dr. M. K. Fagerhol *et al.*), 1185
Influenza Virus : Effect of Urea on A_2 (D. C. Dorman), 780
Information : Optical Processing of (edited by D. K. Pollock *et al.*), *review* by Prof. D. Gabor, 905
Information Explosion (Dr. M. P. Barnett), 585
Infra-red Excitation : Interferometric Raman Spectroscopy using (Dr. G. W. Chantry *et al.*), 1052
Infra-red Spectra of Aqueous Solutions by the Attenuated Total Reflectance Technique (Dr. J. D. S. Goulden and D. J. Manning), 403
Infra-red Spectrophotometric Measurement of the Kinetics of the Action of β-Glucosidase (Prof. F. S. Parker), 975
Ingard, U., *et al.* : Effect of Gas Flow on the Properties of a Plasma Column, 1369
Ingraham, Prof. L. L., *et al.* : Molecular Orbital Evidence for Weiss's Oxyhæmoglobin Structure, 183
Inhaled Radioactive Particles and Gases (Dr. C. N. Davies), 352
Inherited Variants in Serum Ceruloplasmins of the Pig (P. Imlah), 658
Inhibition of Interferon Action by *p*-Fluorophenylalanine (Dr. R. M. Friedman and Dr. J. A. Sonnabend), 366
Inhibition and Excitation in the Acoustic Behaviour of Pholidoptera (M. D. R. Jones), 322
Inhibitor of Adrenal Steroid 11β-Hydroxylase (Dr. M. L. Givner, M. Kraml, D. Dvornik and R. Gaudry), 317
Initiation of Polypeptide Chains in the Reticulocyte Cell-free System (Dr. J. O. Bishop), 40
Inoculum and the Medium on the Growth of *Chlorella pyrenoidosa* : Influence of the (Dr. M. Rodríguez-López), 666
Inorganic Phosphate and Certain Other Anions : Non-enzymatic Interactions of Reduced Coenzyme I with (Prof. S. G. A. Alivisatos *et al.*), 973
Inosinic Acid Pyrophosphorylase Deficiency in Mouse Fibroblasts : Three Degrees of Guanylic Acid (Dr. J. W. Littlefield), 1142
Inositol-deficiency on Yeast with Particular Reference to Chemical Composition of the Cell and of the Cell Wall : Effects of (Dr. S. W. Challinor, Dr. D. M. Power and Dr. R. J. Tonge), 250
Insect Cages, Danger of Spraying Wooden, with Melamine Resins (Dr. T. A. M. Nash and R. J. Kernaghan), 1195
Insect Muscle Pherograms : Phyletic Significance of Some (O. W. Johnson and Prof. W. P. Stephen), 207
Inspection of Alkali, etc., Works, 1023
Institute of Applied Science of Victoria : Annual Report, 1962–63, 1018
Institute of Archæology : Prof. G. W. Dimbleby appointed to the chair of human environment, 576
Institute of Information Scientists : Report of first conference, 820
Institute of Metals : Autumn Meeting, 462
Institute of Personnel Management, national conference, 1124
Institute of Physics and the Physical Society: Colloquium on "Electron Probe X-ray Microanalysis", 462
  Conference on "Luminescence", 462
  Memorial Lectures for 1964, 127
Institution of Electronics : The President's Lecture, 1337
Institution of Mechanical Engineers : The Thomas Hawksley Gold Medal awarded, 578
Insulating Capacity of the Subcutaneous Fat of the Southern Elephant Seal (M. M. Bryden), 1299
Insulin : Electron Paramagnetic Resonance in Single Crystals of Cupric (Prof. A. S. Brill and Dr. J. H. Venable, jun.), 752
Insulin *A*-chain Preparations on the Isolated Rat Diaphragm : Biological Activity of Natural and Synthetic (P. Volfin *et al.*), 408
Insulin on the Liver : Effects of Adenine and Guanine on Hepatic Glucose Release and on the Action of (A. Kaldor *et al.*), 1186
Insulin Secretion *in vitro* by Rabbit Pancrease pre-incubated with β-Hydroxybutyrate : Effect of Glucose on (J. Rojas *et al.*), 758
Insulin and Epinephrine Control of Fatty Acid Release from Adipose Tissue : Effect of Aminonucleoside and Puromycin on (Dr. A. Korner and Dr. M. S. Raben), 1287
Insulins *in vitro* : Biosynthetic Labelling of Mammalian (Dr. K. W. Taylor, *et al.*), 1144
Interaction of Mercuric Ion with Hæmoglobin (R. A. Resnik), 880
Intercellular Space : Lipid Deposition in (Prof. F. M. Scott), 164
Interferometric Observations on the Water/Solids Relation of Activated Sludge Flocs, using a Compression Technique : Some (Prof. P. Coackley and B. Kliger), 77
Interferometric Raman Spectroscopy using Infra-red Excitation (Dr. G. W. Chantry, Dr. H. E. Gebbie and Dr. C. Hilsum), 1052
Interferon : Some Similarities between a Viral Inhibitor of Plant Origin and Chick (Dr. K. H. Fantes and C. F. O'Neill), 1048
Interferon Action by *p*-Fluorophenylalanine : Inhibition of (Dr. R. M. Friedman and Dr. J. A. Sonnabend), 366

Interferon on Uninfected Chick Embryo Fibroblasts : An Effect of (Dr. J. A. Sonnabend), 496
Interferon Production : Effect of Actinomycin *D* on Measles Virus Growth and (C. D. Anderson and Dr. J. G. Atherton), 671
International Association for Analogue Computing, fourth international conference, 351
International Carriage of Dangerous Goods, 1015
International Council for Bird Preservation, British Section 1963 annual report, 459
International Council of Scientific Unions—*Bulletin*, May 1964, 1017
International Institute for Conservation of Historic and Artistic Works : Election of Officers, 819
International Measurement Conference, 351
International Meteorological Organization Prize awarded, 125
International Review of Connective Tissue Research, Vol. I (edited by David A. Hall), *review*, 1320
International Scientific Radio Union (URSI), Tokyo Meeting, 241
Interplanetary Scintillation of Small Diameter Radio Sources (Dr. A. Hewish, Dr. P. F. Scott and D. Wills), 1214
Interrelationships between Amphetamine and *Harmala* Alkaloids (Dr. H. Schmitt and H. Schmitt), 878
Intestinal Cells : Localization of Invertase Activity in Small (A. M. Ugolev et *al.*), 879
Intestinal Content and Intestine of Normal Mice : Inactivation of *MHV*-3 Virus by (Prof. M. Piazza), 1196
Intestines of Freshwater Fish : Evidence for a Dynamic Equilibrium in the Incidence of Cestoda and Acanthocephala in the (Dr. J. C. Chubb et *al.*), 986
Intrafusal Muscle Fibres : Mammalian (Prof. D. Barker and J. P. Hunt), 1193
Intra-ocular Lenses and Implants (Prof. P. Choyce), *review* by Dr. R. A. Weale, 910
Intraventricularly Injected Anticerebral Antibodies on the Histamine-like Substance and Potassium Content of Various Regions of the Brain of the Cat : Effect of (Lj. Mihailović, Dr. B. D. Janković, Dr. B. Beleslin, Dr. K. Mitrović and Lj. Krzalić), 763
Introduction to the Constructive Theory of Functions (Prof. John Todd), *review* by Prof. T. A. A. Broadbent, 114
Introduction to Topology (Prof. Bert Mendelson), *review* by Prof. L. S. Goddard, 443
Inulin-storing Plant Tissues : Effects of Growth-regulating Substances on (Prof. R. L. Wain et *al.*), 504
Invertase Activity in Small Intestinal Cells : Localization of (A. M. Ugolev, N. N. Jesuitova and Dr. P. de Laey), 879
Investigation of Nuclear Weapon Debris with X-ray Microanalyser (J. Sisefsky). 708
In vivo Effect of L-Lysine on Rat Liver Arginase (Dr. D. Cittadini, C. Pietropaolo. D. de Cristofaro and M. d'Ayjello-Caracciolo), 643
In vivo Migration of Colony-forming Units from Shielded Bone Marrow in the Irradiated Mouse (Lieut. G. E. Hanks), 1393
Iodine : Cytochemical and Immunochemical Analysis at the Electron Microscopy Level : Obtaining Contrasting Antibodies by use of (L. B. Mekler et *al.*), 717
Iodine-131 and its Intra-lymphatic Administration with a Fistula on the Thoracic Duct : Exchange Labelling of 'Lipiodol' Ultra-fluids with (J. Liebster and V. Kočandrle), 777
Iodine-131 from Rat and Rabbit Livers : Distribution and Fate of Soluble Proteins labelled with (Dr. V. Bocci), 888
Iodine-131 using Chloramine *T* : Efficient Labelling of Tissue-soluble Proteins with (Dr. V. Bocci), 985
Iodine with Inactivates f_2 Phage and Cells : Resistance of Infectious RNA and Transforming DNA to (Prof. Y. C. Hsu), 152
Ion-exchange Chromatography of Amino-acids : Improvements in the Single Column System (Dr. A. R. Thomson and B. J. Miles), 483
Ion-exchange Method for the Estimation of Strontium-90 in Milk (W. E. Blake, G. Oldham and D. Sumpter), 862
Ionic Changes Responsible for Post-tetanic Hyperpolarization (Dr. P. W. Gage and Dr. J. I. Hubbard), 653
Ionization Detector : A Hydrogen Singing-flame (L. B. Graiff), 856
Ionosphere and Solar Activity : Collision Frequency in the (Prof. W. J. G. Beynon and E. S. O. Jones), 1159
Ionospheric Absorption Events at Conjugate Stations : Fluctuations in (J. K. Hargreaves and H. J. A. Chivers), 963
Iontophoretic Application of Gamma-Aminobutyric Acid on Crayfish Muscle (Prof. A. Takeuchi and N. Takeuchi), 1074
Iron Oxide in the Popliteal Lymph Node of the Rabbit : Distribution of Intravenously Administered Saccharated (D. W. Menzies and G. B. Ryan), 309
Iron–Oxygen Bond in Oxyhæmoglobin : Nature of the (Prof. L. Pauling), 182 ; (Prof. J. J. Weiss), 182
Irradiated in the Infantile Period (Male Rats) : Effect of Chemical Protective Agents (Cysteamine and β-Aminoethylisothiuronium (AET) Cl HCl) and Homologous Testes-DNA on the Death-rate of the Progeny of a First Generation originating from (Dr. N. Savkovič), 1393
Irradiated Mice : Effect of Œstradiol on Bone Marrow Transplantation in Lethally (Dr. J. S. Thompson et *al.*), 265
Irradiated Mice by Sensitized Homologous Spleen Cells : Inhibition of Tumour Growth in (Dr. P. S. Gardner, et *al.*), 1295
Irradiated Mouse : *In vivo* Migration of Colony-forming Units from Shielded Bone Marrow in the (Lieut. G. E. Hanks), 1393
Irradiated, Recovery of Reproductive Ability by Homologous Testes-DNA of Rats, during the Infantile Period (Dr. N. Savković), 1297
Irradiation : High Resistance of Mongolian Gerbils to (Dr. M. C. Chang et *al.*), 536
  Resistance of Fish Embryos to Chronic (V. M. Brown and W. L. Templeton), 1257
Irwin, H., et *al.* : A New Fossil Human Population from the Wadi Halfa Area, Sudan, 341
Iscaki, S., and Raynaud, Prof. M. : Co-precipitating Properties of 3 *S* Fragments derived from Horse Antitoxins, 758
Ishizaka, K., et *al.* : Direct Demonstration of Reagin Activity in Purified γ_{1A}-Globulin, 1046
Isoantigens : Human Pancreas-specific (Prof. R. S. Metzgar), 660
Isocytosine : Co-crystallization of Two Tautomers : Crystal Structure of (J. F. McConnell et *al.*), 399
Isogeneic Murine Skin Grafts following Exposure to Allogeneic Ribonucleic Acid : Rejection of (R. D. Guttmann et *al.*), 196
Isolation of Louping ill Virus from Small Mammals in Ayrshire, Scotland (Dr. C. E. G. Smith, Dr. M. G. R. Varma and Dr. D. McMahon), 992
Isolation of Serologically Active Fucose-containing Oligosaccharides from Human. Blood-group H Substance (Mrs. V. P. Rege, Dr. T. J. Painter, Dr. W. M. Watkins and Prof. W. T. J. Morgan), 360
Isomeric Synthetic Polypeptides : Metabolism of (Dr. T. J. Gill, III, et *al.*), 644
Isomeric Transition in Solid Sodium Tellurate : Thermal Annealing of Tellurium resulting from (D. Dancewicz and Dr. A. Halpern), 856
Isoniazid on Protein Synthesis of *Mycobacteria*, the effect of, 699
Isoprenaline : Mechanism of Reversal of the Vasomotor Effect of (Dr. J. Gutman and Dr. J. Beyth), 1291 ; (Dr. K. R. Butterworth), 1291
Isotope Effect in Radical Reactions (Dr. J. R. Majer, W. D. Capey and Prof. J. C Robb), 294
Isotope Techniques for Hydrology, 1122
Isotopic Composition of Lead in Ores : Relative Distribution of Thorium, Uranium and Lead estimated from the (A. Masuda), 1062
Isotopic Exchange at Equilibrium as a Criterion of Enzymatic Mechanisms (Dr. J. Tze-fei Wong and Prof. G. S. Hanes), 492
Istituto Sperimentale "L Spallanzani" : Medal of Merit awarded, 240
Iswaran, Dr. V., and Rao, Dr. W. V. B. Sundara : Role of Cobalt in Nitrogen Fixation by *Azotobacter chroococcum*, 549
Italy : Marine Levels in South (N. C. Flemming), 1060 ; (A. N. Burton), 1060
Iyengar, R. S. : Shock Wave Propagation from a Nuclear Blast, 746

Mechanism of the Antihypertensive Effect of α-Methyldopa (Prof. R. Imaizumi, M Oka and T. Ohuchi), 982
Mechanisms of Form Vision : Central Adaptation in (Prof. D. M. MacKay), 993

Mechanisms of Inactivation of Single-stranded Virus Nucleic Acids by Heat (W. Ginoza, C. J. Hoelle, K. B. Vessey and C. Carmack), 606
Mechanisms of Sensitization to X-rays of Mammalian Cells by 5-Bromodeoxyuridine (Dr. J. T. Lett, Miss G. Parkins, Dr. P. Alexander and Dr. M. G. Ormerod), 593
Medical Research Council : Formation of three Research Units, 697
    Sir Robert Platt appointed chairman of the Research Board, 347
    Report for 1962–63 (Dr. G. Lapage), 821
    Steroid Reference Collection, 576
Medical Research, Expenditure during the past Decade, 22
Medical Research : The Finance of, 999
Medicated Products : A Comprehensive Scheme for the Quality Control of Drugs and, 701
Mediterranean Area in Historical Times : Stream Deposition in the (Dr. D. Eisma), 1061
Meienhofer, J., *et al.* : Biological Activity of Natural and Synthetic Insulin *A*-chain Preparations on the Isolated Rat Diaphragm, 408
Meiklejohn, Mrs. J., *et al.* : Antibiotic Reactions between African Savanna Species, 1302
Meisinger, Dr. M. A. P., *et al.* : *Para*-O-Methylation of Dopamine in Schizophrenic and Normal Individuals, 154
Meitner, Prof. Lise : *obituary* of Prof. James Franck, 916
Mekler, L. B., *et al.* : Cytochemical and Immunochemical Analysis at the Electron Microscopy Level, 717
Melamine Resins : Danger of Spraying Wooden Insect Cages with (Dr. Y. A. M. Nash and R. J. Kernaghan), 1195
Melanin Granules from Melanocytes to the Cortical Cells of Human Hair : Transfer of (Dr. J. A. Swift), 976
Melanocytes to the Cortical Cells of Human Hair : Transfer of Melanin Granules from (Dr. J. A. Swift), 976
Melehy, Prof. M. A. : Tunnelling-induced Injection in *p-n* Junctions, 1276
Melezitose Locus in *Saccharomyces* : Palatinose Element of the Receptor of the (D. S. Hwang and Prof. C. C. Lindegren), 791
Mellanby, Dr. J., and van Heyningen, Dr. W. E. : Specific Precocious Protective Action of Toxoids, 312
Mellon Institute, Fifty-first Annual Report, 922
Melville, Sir Harry : Contribution of New Instruments to Progress in Chemistry, 949
Melville, Dr. R. : Gynodiœcy in New Zealand *Gentiana*, 203
Memory : Retroactive Interference in Short-term (Dr. H. C. A. Dale), 1408
Memory, Short-term, for Initial Consonant Sounds : Effects of Different Terminal Sounds on (Prof. W. A. Wickelgren), 1199
Menaker, Prof. M. : Frequency of Spontaneous Arousal from Hibernation in Bats, 540
Mendelson, Prof. Bert : Introduction to Topology, *review* by Prof. L. S. Goddard, 443
Meneses, P., *et al.* : Effect of Glucose on Insulin Secretion *in vitro* by Rabbit Pancreas pre-incubated with β-Hydroxybutyrate, 758
Menzies, D. W., *et al.* : Acidophilia of Aortic Elastin in the Child, 195
Menzies, D. W., and Ryan, G. B. : Distribution of Intravenously Administered Saccharated Iron Oxide in the Popliteal Lymph Node of the Rabbit, 309
6-Mercaptopurine : Suppression of Antibody to Endotoxin with : Effect of Antigen Dose (Dr. M. Rubenstein and Dr. S. M. Wolff), 1390
Mercuric Ion with Hæmoglobin : Interaction of (R. A. Resnik), 880
Mercury Electrode : Determination of Electron-oxidation Products using an Auxiliary (Dr. P. Valenta and Dr. J. Koryta), 639
Mercury on Human Erythrocytes : Effects of Tannic Acid and (B. Ospina *et al.*), 788
Meredith, Prof. P. : Recognition of Simple Forms, 1370
Meristems, Growth and Development in Woody Plants (J. A. Romberger), *review* by Prof. C. W. Wardlaw, 562
Meromorphic Functions (Prof. W. K. Hayman), *review* by Prof. T. A. A. Broadbent, 338
Merz, Dr. T., and Migeon, Dr. B. R. : Artefactual Chromatid Aberrations in Untreated and X-ray-treated Human Lymphocytes, 1395
Mesley, R. J. : Advances in Analytical Chemistry and Instrumentation, Vol. 2, *review*, 442
Mesophyll Cells of 'Khapli' Wheat : Occurrence of Lomasomes in (M. S. Manocha and Prof. M. Shaw), 1402
Mesozoic Committee : The British (Dr. D. V. Ager), 1059
Messenger-RNA Synthesis : Selective Alterations of Mammalian : Evidence for Differential Action of Hormones on Gene Transcription (Dr. C. Kidson and Dr. K. S. Kirby), 599
Messenger-RNA Turnover. Actinomycin *D* and (Dr. A. C. Trakatellis *et al.*), 1134
Messiaen, C. M., et Lafon, R. : Les Maladies des Plantes Maraichères, Vol. I, *review* by Dr. R. W. G. Dennis, 1320
Metabolic Activity of Neural Crest Tumours in Tissue Culture (Dr. E. H. La Brosse, J. Belehradek, G. Barski, C. Bohuon and O. Schweisguth), 195
Metabolic Harness on the Plasma Magnesium Concentration in Milking Cows : Effect of Applying a (Dr. H. J. Hendriks), 1306
Metabolism in *Rhodnius prolixus* Stål. : Some Effects of Decapitation on (G. C. Coles), 323
Metabolism of 2,4-Dichlorophenoxyacetic Acid ('2,4-D') by *Aspergillus niger* van Tiegh (J. K. Faulkner and Dr. D. Woodcock), 865
Metabolism of Isomeric Synthetic Polypeptides (Dr. T. J. Gill, III, Dr. D. S. Papermaster and J. F. Mowbray), 644
Metabolism of Lactic Acid during Germination of Pea Seedlings : Formation and (Prof. E. A. Cossins), 989
Metabolism of Phenoxyacetic Acid by *Aspergillus niger* van Tiegh (D. R. Clifford and Dr. D. Woodcock), 763
Metabolite-mediated Control Systems : Regulation of Acid Invertase-levels in Sugar Cane Stalks by Auxin- and (Dr. K. T. Glasziou and J. C. Waldron), 541
Metabolites of Phenylalanine : New (Y. H. Loo and P. Ritman), 1237
Metabolites and Genetic Continuity : Bound Water (Prof. S. J. Webb), 374
Metal Extraction and Mineral Processing : Research on, 237
Metallic Phase in Basic Achondrites : Electron Microprobe Analysis of the (Dr. J. F. Lovering), 70
Metallographs : Bausch and Lomb, 1337
Metallurgy : Hundred Years of (W. H. Dennis), *review* by Prof. F. C. Thompson, 337
Metals : Distribution of Twins around a Microhardness Indenter in Close-packed Hexagonal (P. G. Partridge), 634
Metamorphism in Britain : Age of Caledonian Orogeny and (F. J. Fitch *et al.*), 275
Metastability of Amorphous Structures (Prof. M. H. Cohen and Dr. D. Turnbull), 964
Metastrongylus sp. : Transmission of Pig Lungworms (S. E. Jaggers and Dr. I. V. Herbert), 987
Metcalfe, Dr. C. R. : Vegetative Anatomy of Plants, *review*, 1005
Meteorites : Chlorine-36 produced by Neutron Capture in (Prof. P. S. Goel), 1162
    Luminescence of Enstatite Achondrite (C. J. Derham *et al.*), 134
Methanolysis of 2,4-Dinitrophenyl *p*-Toluene Sulphonate (A. Kirkien-Konasiewicz, G. Sammy and Prof. A. Maccoll), 637
Methicillin-resistant Strains of *Staphylococcus aureus* : *L* Form Induction of Naturally Occurring (Dr. B. M. Kagan *et al.*), 1031
Methionine-treated Rats : Occurrence of Homoserine in the Liver of Ethionine- or (Dr. F. Chatagner), 1177
Method for Describing the Packing Texture of Clastic Sediments (I. J. Smalley), 281
Méthodes Statistiques à l'Usage des Médecins et des Biologistes (D. Schwartz), *review* by Prof. P. Armitage, 686
Methods of Quantitative Inorganic Analysis (K. Kodama), *review* by A. D. Wilson, 559
Methot, Dr. A. L., *et al.* : Hepatic Inactivation of Angiotensin, 531
Methylation in Mutation of *Escherichia coli* and *Drosophila* : Ethylation versus (Dr. T. Alderson), 1404
Para-O-Methylation of Dopamine in Schizophrenic and Normal Individuals (F. A. Kuehl, jun., M. Hichens, R. E. Ormond, Dr. M. A. P. Meisinger, P. H. Gale, V. J. Cirillo and Dr. N. G. Brink), 154
α-Methyldopa : Mechanism of the Antihypertensive Effect of (Prof. R. Imaizumi *et al.*), 982
Methyl Linoleate : Saturated Hydrocarbons from Autoxidizing (R. J. Horvat *et al.*), 523
Methyl Linolenate by Metastable Argon Atoms : Anomalous Ionization of : Possible Linolenic Acid Participation in Photosynthetic Reactions (A. G. Vereshchagin and G. V. Novitskaya), 1384
Metric to Inch Conversion (W. M. Anderson and B. E. Robinson), 551
Metson, P., *et al.* : Fall-out in London Rain Water, 617
Metzgar, Prof. R. S. : Human Pancreas-specific Isoantigens, 660
Meyer, Dr. P., *et al.* : Hepatic Inactivation of Angiotensin, 531
Meyer, R., *et al.* : Impact of the Laser on Dental Caries, 417
Michaelis Complex : Absorption Spectrum of the Crystal of D-Amino-acid Oxidase (Prof. K. Yagi and T. Ozawa), 864
Michigan State University : Appointment, 1225
Microbiological Research Establishment, Porton : Dr. D. W. W. Henderson, retires, 575
    Dr. C. E. G. Smith appointed director, 575
Microbiologists : Varro and the Small Beasts : A Bimillennium for (Dr. D. F. Cheesman), 911
Micrococcus radiodurans : Radiation Resistance and Deoxyribonucleic Acid Base Composition of (Dr. B. E. B. Moseley and Dr. A. H. Schein), 1298
Micro-crystal Formation on the Electron Spin Resonance Spectra of αα-Diphenyl-β-picrylhydrazyl in Various Frozen Solvents : Effect of (Dr. P. B. Ayscough, Dr. H. E. Evans and Dr. A. P. McCann), 1378
Microdensitometer : Measurements of Deoxyribonucleic Acid on Mammalian Germ Cells using the Integrating (Dr. J. L. Burks and A. H. Bakken), 325
Micro-electrophoresis : Optical Correction in (E. S. Hall), 1371
Microhardness Indenter in Close-packed Hexagonal Metals : Distribution of Twins around a (P. G. Partridge), 634
Microwave Techniques for the Determination of Bound Water : Use of (Dr. P. O. Vogelhut), 1169
"Microwaves, Circuit Theory and Information Theory", international conference, 24
Migeon, Dr. B. R., and Merz, Dr. T. : Artefactual Chromatid Aberrations in Untreated and X-ray-treated Human Lymphocytes, 1395
Migration, *In vivo*, of Colony-forming Units from Shielded Bone Marrow in the Irradiated Mouse (Lieut. G. E. Hanks), 1393
Mihailović, Dr. Lj., *et al.* : Effect of Intraventricularly Injected Anticerebral Antibodies on the Histamine-like Substance and Potassium Content of Various Regions of the Brain of the Cat, 763
Mildews : Thermal and Translocated Induction of Endophytic Mycelium in two Powdery (W. R. Jarvis), 895
Miles, B. J., *et al.* : Amino-acid Sequence around the Reactive Thiol Groups of Adenosine Triphosphate-creatine Phosphotransferase, 267
Miles, B. J., and Thomson, Dr. A. R. : Ion-exchange Chromatography of Amino-acids : Improvements in the Single Column System, 483
Milgrom, Dr. F., *et al.* : Homotransplantation Antibodies detected by Mixed Agglutination with Cell Culture Monolayers, 313
Milk : An Ion-exchange Method for the Estimation of Strontium-90 in (W. E. Blake *et al.*), 862
Milk Iron in a Lactating Marsupial, 350
Milking Cows : Effect of Applying a Metabolic Harness on the Plasma Magnesium Concentration in (Dr. H. J. Hendriks), 1306
Millen, Dr. D. J. : Atomic Structure and Chemical Bonding, *review*, 114
Miller, A., *et al.* : Molecular Structure of α-Keratin, 1231
Miller, A. R., High Salinity in Sea Water, 590
Miller, David : Thomas Cawthron and the Cawthron Institute, *review* by Dr. G. W. Cooke, 802
Miller, Dr. J. A., *et al.* : Age of Caledonian Orogeny and Metamorphism in Britain, 275
Milliez, Prof. P., *et al.* : Hepatic Inactivation of Angiotensin, 531
Millikan, Dr. D. F., and Pickett, Dr. E. E. : Some Physical Properties of Interfering Substances associated with the Alkaline Hydrolysis of RNA from Plant Leaf Tissue, 190
Millott, Prof. N. : Pigmentary System of *Diadema antillarum* Philippi, 206
Milne, D. K., and Mathewson, D. S. : Pattern in the Large-scale Distribution of Galactic Polarized Radio Emission, 1273
Milner, H. B. : Blast-furnace Cement in South Africa, 1024
Milner, O. I. : Analysis of Petroleum for Trace Elements, *review* by E. Thornton, 685
Mineral Processing Congress, seventh international, 462
Mining and Geology : Technical Assistance for Overseas, 331
Ministry of Housing and Local Government—Scottish Development Department. Alkali, etc., 100th Annual Report, 1963, 1023
Miocene Lavas of North-Eastern Oregon, South-Eastern Washington and West-Central Idaho : Structural Implications of Palæomagnetism in (N. D. Watkins), 830
Miocene Mammals from North-east Uganda : More Fossil Primates and other (Dr. W. W. Bishop), 1327
Mirids and Other Insect Pests of Cocoa (P. F. Entwistle), 922
Mitchell, Dr. J. F., *et al.* : Identity of the Cerebellar Factor, 1388
Mitchell, jun., Will (edited by) : Fuel Cells, *review* by Sir Eric Rideal, 1315
Mitlin, N., and Vicker, D. H. : Guanine in the Excreta of the Boll Weevil, 1403
Mitochondria : Chloramphenicol as an Inhibitor of Energy-linked Processes in Maize (C. D. Stoner *et al.*), 258
    Electron Histochemical Examination of Oxidative Enzymes and (Dr. K. Ogawa and Prof. R. J. Barrnett), 724
Mitochondria of the Double-walled Viral Membrane in *Saccharomyces* : Origin from (Prof. C. C. Lindegren and Y. N. Bang), 431
Mitochondrial Morphogenesis (Dr. O. A. Schjeide, R. G. McCandless and R. J. Munn), 158
Mitochondrion-rich Cells of the Dog Thyroid : Calcitonin Production and the (Dr. G. V. Foster *et al.*), 1029

Mitrović, Dr. K., et *al.* : Effect of Intraventricularly Injected Anticerebral Antibodies on the Histamine-like Substance and Potassium Content of Various Regions of the Brain of the Cat, 763
Miwa, Prof. T., et *al.* : Specificities of Several Acid Phosphatases from Plant Sources, 939
Mode of Multiplication of *Theileria* in Cultures of Bovine Lymphocytic Cells (Dr. L. Hulliger, Dr. J. K. H. Wilde, C. G. D. Brown and Miss Leslie Turner), 728
Model : A Case of an Inappropriate (Dr. M. Hammerton), 63
"Models for the Perception of Speech and Visual Forms", symposium, 1337
Modern Glass Technology, 1341
Modern Packaging Films, symposium, 1228
Modest, Dr. E. J., et *al.* : Structural Investigation of 4-[(-Amino-5-pyrimidinyl)-imino]-2-penten-2-ol., 970
Modification of the Radiation Effect on Ascitic Tumour Cells by Pharmacological Agents injected Intravenously (Dr. J. N. Correa and Dr. J. R. Andrews), 200
Mohanty, J. N. : Edmund Husserl's Theory of Meaning, *review* by F. I. G. Rawlins, 680
Molecular Basis of Self-duplication : Deoxyribonucleic Acid and the (Prof. B. Commoner), 486
Molecular Geometry of Androsterone (Dr. D. A. Norton and J. M. Ohrt), 754
Molecular Orbital Evidence for Weiss's Oxyhæmoglobin Structure (R. O. Viale, G. M. Maggiora and Prof. L. L. Ingraham), 183
Molecular Structure of α-Keratin (R. D. B. Fraser, T. P. MacRae and A. Miller), 1231
Molecular Structure of Phosphobenzene (Dr. J. J. Daly and L. Maier), 1167
Mollison, Prof. P. L., and Polley, M. J. : Uptake of γ-Globulin and Complement by Red Cells exposed to Serum at Low Ionic Strength, 535
Mollusc : A Non-cholinergic Synaptic Inhibition in the Central Nervous System of a (Dr. H. M. Gerschenfeld), 415
Molomut, Dr. M., et *al.* : Survival of Ehrlich's Ascites Carcinoma Cells at High Ultra-Centrifugal Forces, 740
Molybdenum Disilicide : Role of Silica in the Oxidation Resistance of (Dr. G. Todd and E. Parry), 967
Molybdenum Disulphide and Water : Reaction between (Dr. P. Cannon and Dr. F. J. Norton), 750
Monash University : Chair of mathematical statistics, 457
Money for Research and Research for Money (Substance of an address before the fifth Annual Congress of the Professions by Dr. A. T. Waterman, 1964), 563
Mongolian Gerbils to Irradiation : High Resistance of (Dr. M. C. Chang, D. M. Hunt and C. Turbyfill), 536
Monier-Williams, Dr. G. W. : *obituary* by T. McLachlan, 346
Mönig, H., and Koch, Prof. R. : Electron Spin Resonance Investigations of Ultraviolet and X-irradiated Bovine Serum Albumin, 859
Monkeys : Mallophaga on Catarrhine : *Colobus guereza*, a Natural Host of *Procavicola colobi* (Dr. H. J. Kuhn and H. W. Ludwig), 424
Monkhouse, Prof. F. J. (edited by) : A Survey of Southampton and its Region, 956
Monolayer Properties : Effect of the Spreading Solvent on (D. C. Walker and Dr. H. E. Ries, jun.), 292

Mossop, Dr. S. C. : Volcanic Dust collected at an Altitude of 20 km, 824
Motor Axons of the Crab, *Carcinus* : Lability of the Action Potential and the Recovery Cycle from Isolated (R. A. Chapman), 872
Motor End-plates and their Relationship to Muscle Fibre Injury : New (Dr. D. G. Gwyn and Dr. J. T. Aitken), 651
Motor-nerve Terminals : Direct Evidence for an Action of Acetylcholine on (Dr. J. I. Hubbard and Dr. T. Yokota), 1072
Moulting Frequency of a Deep-sea Crustacean, *Euphausia pacifica*(Dr. R. Lasker), 96
Mowbray, J. F., et *al.* : Metabolism of Isomeric Synthetic Polypeptides, 644
Mozell, Prof. M. M. : Evidence for Sorption as a Mechanism of the Olfactory Analysis of Vapours, 1181
Muckle, T. J. : Protein Components of Amyloid, 773
Mucopolysaccharides by Cell Cultures of Human Fibroblasts : Effects of 17-β-œstradiol on the Production of Acid (Prof. L. Ozzello and Dr. J. Y. Bembry), 80
Mucoprotein : Specific Inhibition of Anti-*D* by Human Urinary (Dr. H. W. Johnson and M. C. Dodd), 1082
Mucosa, Intestinal, of the Mouse : Effect of a Diet containing Sodium Deoxycholate on the (Dr. R. J. M. Fry and Dr. E. Staffeldt), 1396
Mucosa of the Frog : Effect of Thiocyanate on Secretion of Acid and Uptake of Oxygen by Gastric (W. H. Bannister), 978
Mueller, Dr. R. F. : Stability of Hydrogen Compounds on Venus, 625
Muirhead, Dr. H., et *al.* : Structure of Hæmoglobin : an X-ray Examination of reduced Horse Hæmoglobin, 687
Mulholland, Dr. T. B. : awarded a Carnegie Institution fellowship, 1121
Mullard Research Laboratories : Dr. K. Hoselitz appointed deputy director, 576
Müller, Dr. D. G. : Life-cycle of *Ectocarpus siliculosus* from Naples, Italy, 1402
Multiplication of Rauscher Virus in Cultures of Mouse Kidney Cells (J. Peries, J. P. Levy, Dr. M. Boiron and Prof. J. Bernard), 672
Multipulse Potentio-Dynamic Method : Anion Adsorption on Platinum by the (S. Gilman), 1130
Muniak, S. E., et *al.* : Concentrations of Cæsium-137, Rhodium-102 and Manganese-54 in Surface Air, 470
Munn, R. J., et *al.* : Mitochondrial Morphogenesis, 158
Munro, Dr. H. N., and Downie, Dr. E. D. : Relationship of Liver Composition to Intensity of Protein Metabolism in Different Mammals, 603
Munro, P. E., et *al.* : Antibiotic Reactions between African Savanna Species, 1302
Munson, Dr. R. J., and Bridges, Dr. B. A. : Segregation of Radiation-induced Mutations in *Escherichia coli*, 270
Murata, Prof. K., et *al.* : Antioxidants isolated from Fermented Soybeans (Tempeh), 870
Murray, L. R., et *al.* : Enolase and Fluorophosphate (**202**, 1331) ; *erratum*, 24
Muscarinic Receptors of Renshaw Cells : Nicotinic and (Dr. D. R. Curtis and R. W. Ryall), 652
Muscle Fibre Injury : New Motor End-plates and their Relationship to (Dr. D. G. Gwyn and Dr. J. T. Aitken), 651
Muscle Fibres : Mammalian Intrafusal (Prof. D. Barker and J. P. Hunt), 1193
Muscle Membrane : Acetylcholine Receptors in (Prof. A. Portela, et *al*), 1179
  Potassium Effects on Cæsium–Choline Interactions in (Prof. A. Portela et *al.*), 1071
Muscle Movement : Cortical Cell Activity and : Reciprocal Activation and Inhibition of Cortical Neurones and Voluntary Movements in Man : (Dr. C.-L. Li and Dr. J. M. Tew, jun.), 264
Muscle Spindle Endings by β-Axon Stimulation : Excitation of Primary (Dr. G. L. Kidd), 1248
Museums Association (Dr. F. S. Wallis), 706
Museums Association Annual Report 1963–64, 698
Museums Journal, **64**, No. 1, 698
Mushroom Hunter's Field Guide (Prof. A. H. Smith), revised and enlarged edition, *review* by D. A. Reid, 1320
Mutagenic Action of Hyponitrous Acid and Glucose Oxime (Prof. K. Yamafuji and Dr. K. Watanabe), 409
Mutant Expression and Canalization (Dr. W. Scharloo), 1095
Müting, Dr. D., and Bette, L. : Free α-Amino-N Content of Peripheric and Hepatic Venous Blood of Normal Adults, 192
Muzik, Prof. T. J., and Mauldin, W. G. : Formative Response of *Amsinckia intermedia* to the Interrelated Effects of Low Temperature, Thiamin and 2,4-Dichlorophenoxyacetic Acid, 427
Mycelium in two Powdery Mildews : Thermal and Translocated Induction of Endophytic (W. R. Jarvis), 895
Mycobacterium smegmatis and *Aerobacter aerogenes* : Relationship between the Products of Aromatic Biosynthesis in (Dr. C. Ratledge), 428
'Myleran' : Shortening of the Span of Life of Rats by (Dr. A. Dunjic), 887
'Myleran' for the Determination of the Size of DNA Molecules in Cells : Utilization of Labelled (Dr. W. G. Verly and A. Petitpas-Dewandre), 865
Myoepithelial Cells of Rat Salivary Glands : Histochemical Localization of Alkaline Phosphatase and Adenosine Triphosphatase in the (M. Shear), 770
Myogenesis by Actinomycin *D* : Time-dependent Inhibition of (Dr. P. Pietsch), 1177
Myometrial Adenosine Triphosphatase : Inhibitory Effect of Progesterone on Activity of Human (Dr. D. Kumar et *al.*), 83
Myopathic Syndrome associated with Pituitary Activation of Thymus : Experimental (Dr. G. J. Svet-Moldavsky, N. Spector and L. Ravkina), 771
Mystery of the Cosmic Helium Abundance (Prof. F. Hoyle and Dr. R. J. Tayler), 1108

NABNEY, J., and Nesbitt, Dr. B. F. : Determination of the Aflatoxins, 862
Nadal, C., et *al.* : Slow Alpha$_2$-Globulin of Rat Serum, 1182

Parker, W., and Baumgartner, H. : Electrodeposition Method for the Preparation of Electron Microscope Specimens, 715
Parkins, Miss G., et *al.* : Mechanisms of Sensitization to X-rays of Mammalian Cells by 5-Bromodeoxyuridine, 593

Parliamentary and Scientific, Second Conference (Sir Willis Jackson), 118
Parry, D. G., et *al.* : Biosynthetic Labelling of Mammalian Insulins *in vitro*, 1144
Parry, E., and Todd, Dr. G. : Role of Silica in the Oxidation Resistance of Molybdenum Disilicide, 967
Particle Flux in the Auroral Zone : Periodic Precipitation of the (Dr. R. N. Singh), 69
Particle Size in Dust : Distribution of (A. D. Joffe) ; 1057 ; (J. Cartwright), 1057
Partridge, P. G. : Distribution of Twins around a Microhardness Indenter in Close-packed Hexagonal Metals, 634
Pasik, Dr. P., and Pasik, Dr. T. : Optokinetic Nystagmus : an Unlearned Response Altered by Section of Chiasma and Corpus Callosum in Monkeys, 609
Pasik, Dr. T., and Pasik, Dr. P. : Optokinetic Nystagmus : an Unlearned Response Altered by Section of Chiasma and Corpus Callosum in Monkeys, 609
Pasternak, G., et *al.* : Resistance against Carcinomas of the Skin induced by Dimethylbenzanthracene (DMBA) in Mice of the Strain XVII/*Bln*, 307
Pasteurella tularensis : Factor required for Growth Initiation of (Prof. J. Mager), 898
Pasture Yield : An Improved Electronic Instrument for Estimation of (Dr. M. B. Alcock), 1309
Paterson, E. B., and Haskell, Dr. G. : Quick Preparation of Corolla Chromosomes from Flower Buds, 673
Paterson, Dr. S. : Light from Shocked and Detonating Powders, 1057
Pattern of Cell Migration during Cortical Histogenesis (Dr. M. Berry, Dr. A. W. Rogers and Prof. J. T. Eayrs), 591
Pattern and Colour in the Stabilized Retinal Image : Perception of (G. W. Beeler et *al.*), 1200
Paul Instrument Fund Award, 1018
Paul, Dr. W. E., and Odell, Dr. W. D. : Radiation Inactivation of the Immunological Biological Activities of Human Chorionic Gonadotropin, 979
Pauling, Prof. L. : Nature of the Iron-Oxygen Bond in Oxyhæmoglobin, 182
Pauls, F. P., et *al.* : Survival of *Shigella* in Sea Water, 213
Payne, Dr. L. N., and Biggs, Dr. P. M. : Difference in Susceptibility to Lymphoid Leukosis Virus and Rous Sarcoma Virus between Cells from Two Inbred Lines of Domestic Fowl, 1306
Pea Seedlings : Formation and Metabolism of Lactic Acid during Germination of (Prof. E. A. Cossins), 989
Pea Stems in Maleate Buffer : Prevention by 2,4-Dichlorophenoxyacetic Acid of an Increase in the Rate of Phosphate Utilization, caused by the Prolonged Treatment of Segments of (J. M. Palmer and Prof. G. E. Blackman), 526
Pear Seedlings to N-Dimethylaminosuccinamic Acid, a Growth Retardant : Responses of (H. J. Brooks), 1303
Pearse, Dr. A. G. E., et *al.* : Calcitonin Production and the Mitochondrion-rich Cells of the Dog Thyroid, 1029
Pecsok, Dr. R. L., et *al.* : Liquid-gas Interface Effects in Gas Chromatography, 1279
Pectin and Methylated Uronic Acid Residues : A Proposed Pathway for the Biosynthesis of (Dr. F. A. Loewus), 1175
Peer, P., and Seneca, Prof. H. : Immuno-clinical Classification of *Staphylococcus pyogenes aureus*, 787
Pegoràro, L., et *al.* : Proliferation and Maturation Defect in Acute Leukæmia Cells, 92
Penco, S., et *al.* : Structure and Synthesis of Distamycin *A*, 1064
Pendular Moisture in Packings of Equal Spheres (Prof. C. C. Harris and Dr. N. R. Morrow), 706
Pendulum : An Electrically Charged Torque (Dr. E. J. Saxl), 136
Pengelley, E. T. : Responses of a New Hibernator (*Citellus variegatus*) to Controlled Environments, 892
Penguins at Cape Crozier : Emperor (Dr. B. Stonehouse), 849
D-Penicillamine : Pyridoxine Deficiency in the Rat produced by (A. M. Asatoor), 1382
L-Penicillamine on Sarcoma-180 : Growth-retarding Effect of Oral (Dr. M. L. Littman et *al.*), 726
Penicillin Deacylase Enzyme of *Escherichia coli* : Properties of the (M. Cole), 519
Penicillins : Quinacillin : A Comparison with other Penicillinase-resistant (Dr. J. T. Smith et *al.*), 1148
Penicillins, Chloramphenicol and Tetracycline : Development *in vitro* of Bacterial Cross-resistance involving (R. Sutherland et *al.*), 548
Penniman, T. K. : Ancient Iraq, *review*, 802
Pennington, G. W., and Lambert, M. : Isolation and Identification of the 20β-Hydroxy Derivatives of 6β-Hydroxycortisol and 6β-Hydroxycortisone in Liquor Amnii, 656
PNA, DNA and Protein Contents in a Rapidly Differentiating System, the Rat Tapeworm (*Hymenolepis diminuta*), (Dr. T. W. Lee and Prof. J. W. Campbell), 661
Pentacyanocobaltate Ions and with Reduced Vitamin B_{12} : Reaction of Tetrafluoroethylene with (M. J. Mays and Prof. G. Wilkinson), 1167
Pentasulphur Triimides : Completion of a Class of Cyclic Sulphur Imides (Dr. H. Heal and J. Kane), 971
Penzias, A. A., et *al.* : OH Absorption Spectra in Sagittarius, 65
Perceived Form : Dynamic Distortions of (Prof. D. M. MacKay), 1097
Perception of Pattern and Colour in the Stabilized Retinal Image (G. W. Beeler, D. H. Fender, P. S. Nobel and C. R. Evans), 1200
Perennials : Special Problems in Studying Woody (Prof. R. H. Stoughton), 1229
Pérez, J. C., et *al.* : Acetylcholine Receptors in Muscle Membrane, 1179
  Potassium Effects of Cæsium-Choline Interactions in Muscle Membrane, 1071
Pergamon Moon Globe, *review* by Dr. H. C. King, 1230
Peries, J., et *al.* : Multiplication of Rauscher Virus in Cultures of Mouse Kidney Cells, 672
Periodic Precipitation of the Particle Flux in the Auroral Zone (Dr. R. N. Singh), 69
Periodicity of Absorption Properties in Pigments based on Vitamin A_2 from Fish Retinæ (Dr. C. D. B. Bridges), 303
Periplaneta americana : Effects of Brain and Corpus Cardiacum Extracts on Hæmolymph Trehalose of the Cockroach (Prof. C. L. Ralph and R. McCarthy), 1195
Perlmann, Dr. P., et *al.* : Phytohæmagglutinin-induced Cytotoxic Action of Normal Lymphoid Cells on Cells in Tissue Culture, 841
Permeability Control in Chilled Bacteria : Effect of Magnesium on (R. E. Strange), 1304
Permeability Factor in Pollen Extracts Active in Non-sensitized Mice (Prof. L. S. Kind, W. Richards, A. T. Smith and P. Ellman), 1390
Perrone, J. C., et *al.* : Fractionation of Trypsin by Paper Electrophoresis, 43
Personnel Dosimetry Techniques for External Radiation : Proceedings of the Madrid Symposium, April, 1963, *review* by Dr. D. Hughes, 1316
Pertussis Vaccine : Preparation of Soluble (P. van Hemert, A. L. van Wezel and H. H. Cohen), 774
Perutz, Dr. M. F., et *al.* : Structure of Hæmoglobin : An X-ray Examination of reduced Horse Hæmoglobin, 687
Pesticides and Other Toxic Chemicals : Advisory Committee on, 22
Peters, Prof. B. G. : The Lower Metazoa, *review*, 684
Peters, Sir Rudolph, et *al.* : Enolase and Fluorophosphate (202, 1331), *erratum*, 24
Peters, Prof. R. H., and Hearle, Dr. J. W. S. (edited by) : Fibre Structure, *review* by H. J. Woods, 1001
Peters, Dr. W. : Pigment Formation and Nuclear Division on Chloroquine-resistant Malaria Parasites (*Plasmodium berghei*, Vincke and Lips, 1948), 1290
Petersen, D. F., and Anderson, E. C. : Quantity Production of Synchronized Mammalian Cells in Suspension Culture, 642
Petersen, J. A., and Burdon-Jones, Dr. C. : Another Giant Enteropneust from the Atlantic, 97
Petitpas-Dewandre, A., and Verley, Dr. W. G. : Utilization of Labelled 'Myleran' for the Determination of the Size of DNA Molecules in Cells, 865
Petroleum for Trace Elements : Analysis of (O. I. Milner), *review* by E. Thornton, 685
Petroleum Information Bureau : *U.K. Petroleum Industry Statistics* : *Consumption and Refinary Production*, 1962 *and* 1963, 459
Petunia Pollen : Enzyme Activation in Germinating (R. G. Stanley and H. F. Linskens), 542
'Pevikon C-870' : Soluble Liver Proteins Fractionation by Zone Electrophoresis on (Dr. V. Bocci), 775
Pfeffer, Dr. M., et *al.* : Pyridoxal-β-Cyanoalanine Relation in the Rat, 1286
Pfizer, Ltd., New Research Building, 1335
*p*H-stat Titration of a Polyfunctional Reactant by a Competitive 'Ligandee' : Theory of the (Dr. S. Katz), 858
Phage and Cells : Resistance of Infectious RNA and Transforming DNA to Iodine which Inactivates f_2 (Prof. Y.-C. Hsu), 152
Pharmacological Agents injected intravenously : Modification of the Radiation Effect on Ascitic Tumour Cells by (Dr. J. N. Correa and Dr. J. R. Andrews), 200
Phatak, T. C., et *al.* : Thermionic Emission and Heat of Hydration of Lime, 61
Phatak, T. C., and Chatterji, A. K. : Reaction between Portland Cement Clinker and Water, 138
Phenetic and Phylogenetic Classification (Dr. V. H. Heywood and Dr. J. McNeill), 1220
Phenoxyacetic Acid by *Aspergillus niger* van Tiegh : Metabolism of (D. R. Clifford and Dr. D. Woodcock), 763
Phenylalanine : New Metabolites of (Y. H. Loo and P. Ritman), 1237
Pherograms : Phyletic Significance of Some Insect Muscle (O. W. Johnson and Prof. W. P. Stephen), 207
Phillips, D., and Majer, Dr. J. R. : Disproportionation of Halogenated Alkyl Radicals, 1165
Phillips, Dr. R. J. N. : Annual Review of Nuclear Science, Vol. 13, *review*, 114
Philosophy of Science : The Delaware Seminar. Vol. 1, 1961–1962 (edited by Bernard Baumrin), *review* by G. Buchdahl, 110
Phloem : Cytoplasm Exudate from Cut (Dr. T. Thaine), 544
Pholidoptera : Inhibition and Excitation in the Acoustic Behaviour of (M. D. R. Jones), 322
Phosphate Ions in Soil Solutions : Effect of Soil/Solution Ratio on Determining the Chemical Potentials of (S. Larsen and A. E. Widdowson), 942
Phosphate, Soluble, in Soil and Uptake by Plants (Dr. A. Wild), 326
Phosphate Utilization, caused by the Prolonged Treatment of Segments of Pea Stems in Maleate Buffer : Prevention by 2,4-Dichlorophenoxyacetic Acid of an Increase in the Rate of (J. M. Palmer and Prof. G. E. Blackman), 526
Phosphobenzene : Molecular Structure of (Dr. J. J. Daly and L. Maier), 1167
Phospholipid in the Development of the Slow Muscle Contracting Activity of Human Plasma : Possible Role of a (Dr. Y. Gabr), 765
Phosphorus : Influence of Nitrogen on the Availability of Fertilizer (Dr. G. Dev), 899
Phosphorus in Deoxythymidine Polynucleotides : Nuclear Magnetic Resonance of (Dr. M. Mandel and Dr. J. W. Westley), 301
Phosphotransferase : Amino-acid Sequence Around the Reactive Thiol Groups of Adenosine Triphosphate-creatine (Dr. A. R. Thomson et *al.*), 267
Photic Regulation of 5-Hydroxytryptophan Decarboxylase in the Rat Pineal Gland : Neural and (Dr. S. H. Snyder et *al.*), 981
Photochemistry : Advances in, Vol. 1 (edited by W. Albert Noyes, jun., G. S. Hammond and J. N. Pitts, jun.), *review* by Dr. H. M. Frey, 225
Photolysis of Nitrosyl Chloride by Ultra-violet Radiation (Dr. R. P. Wayne), 516
Photoperiod on Cyclic Patterns of Body Temperature in the Quail : Effect of (A. E. Woodard and F. B. Mather), 422
Photoperiodism in the House Finch demonstrated by Interrupted-night Experiments : Circadian Control of (Dr. W. M. Hamner), 1400
Photosynthetic Capacity : A Persistent Diurnal Rhythm in (Prof. J. D. Palmer et *al.*), 1087
Phototaxis in *Chlamydomonas snowiae* by Indolyl-3-acetic Acid and Ethylenediamine Tetraacetic Acid : Induction of (I. Chorin-Kirsh and Dr. A. M. Mayer), 1085
Phyletic Significance of Some Insect Muscle Pherograms (O. W. Johnson and Prof. W. P. Stephen), 207
Phylogenetic Classification : Phenetic and (Dr. V. H. Heywood and Dr. J. McNeill), 1220
Physical Biochemistry Group, meeting, 462
Physical Properties of Interfering Substances associated with the Alkaline Hydrolysis of RNA from Plant Leaf Tissue : Some (Dr. D. F. Millikan and Dr. E. E. Pickett), 190
Physically Fit Subjects : Lack of Artificial Acclimatization to Heat in (Dr. J. E. Greenleaf), 1072
Physics Conference held by the Swedish National Committee for Physics, 1123
Physics in the United States, 22
Physics of Plant Environment (edited by W. R. Van Wijk), *review* by Dr. J. L. Monteith, 444
Physiological and Genetic Effects of 8-Azaguanine on *Aspergillus nidulans* (Dr. A. T. Bull and Dr. B. M. Faulkner), 506
Physiologie, Comportement et Écologie des Acridiens en Rapport avec la Phase (Colloques Internationaux du Centre National de la Recherche Scientifique, No. 114, 1962), *review* by D. R. Ragge, 686
Phytohæmagglutinin-induced Cytotoxic Action of Normal Lymphoid Cells on Cells in Tissue Culture (Dr. G. Holm, Dr. P. Perlmann and Dr. B. Werner), 841
Phytophthora : A Factor controlling Sexual Reproduction in (J. A. Leal, et *al.*), 545
Piaget, Jean et Fraisse, Paul (sous la direction de) : Traité de Psychologie Expérimentale, Vols. 1, 2, 5 and 6, *review* by Prof. O. L. Zangwill, 109
Piazza, Prof. M. : Inactivation of *MHV*-3 Virus by Intestinal Content and Intestine of Normal Mice, 1196
Picciotto, E., et *al.* : Rate of Accumulation of Snow at the South Pole as Determined by Radioactive Measurements, 393
Pickett, Dr. E. E., and Millikan, Dr. D. F. : Some Physical Properties of Interfering Substances associated with the Alkaline Hydrolysis of RNA from Plant Leaf Tissues, 190
Pietropaolo, C., et *al.* : *In vivo* Effect of L-Lysine on Rat Liver Arginase, 643
Pietsch, Dr. P. : Time-dependent Inhibition of Myogenesis by Actinomycin *D*, 1177
Pig Lungworms (*Metastrongylus* sp.) : Transmission of (S. E. Jaggers and Dr. I. V. Herbert), 987

Pigment Formation and Nuclear Division in Chloroquine-resistant Malaria Parasites (*Plasmodium berghei*, Vincke and Lips, 1948 (Dr. W. Peters), 1290
Pigmentary System of *Diadema antillarum* Philippi (Prof. N. Millott), 206
Pileri, A., et *al.* : Proliferation and Maturation Defect in Acute Leukæmia Cells, 92
Pillai, K. C., et *al.* : Plutonium in the Marine Environment, 568
Pineal Body of the Rat : Flow of Blood to the (Prof. H. Goldman and Dr. R. J. Wurtman), 87
Pineal Gland : Neural and Photic Regulation of 5-Hydroxytryptophan Decarboxylase in the Rat (Dr. S. H. Snyder et *al.*), 981
Pinguinain by Gel Filtration : Purification of (Dr. E. Toro-Goyco and M. Matos), 82
Pirelli, A., et *al.* : Structure and Synthesis of Distamycin *A*, 1064
Pirenne, Dr. M. H. : The Aging Eye, *review*, 1209
Pithomyces chartarum : Free Sugars in Spores of (I. G. Andrew), 204
Pitt-Rivers, R., and Trotter, W. R. : The Thyroid Gland, Vols. 1 and 2, *review*, 1210
Pitts, jun., J. N., et *al.* (edited by) : Advances in Photochemistry, Vol. 1, *review* by Dr. H. M. Frey, 225
Pittsburgh Diffraction Conference, twenty-second annual conference, 1228
Pituitary Activation of Thymus : Experimental Myopathic Syndrome associated with (Dr. G. J. Svet-Moldavsky et *al.*), 771
Place of Biochemistry in the New Universities (Prof. E. A. Dawes, 131
Placenta : Selective and Directional Transfer of 7*S* γ_2-Globulin across the Human (Prof. D. Gitlin et *al.*), 86
Planck, The Max, Medallists of the German Physical Society, 21
Plankton : Alpha-Radioactivity of (R. D. Cherry), 139
  Effect of Low-salinity Water on the Vertical Migration of Estuarine (J. R. Grindley), 781
Planning, 30, No. 482 : *Teachers for the Commonwealth—the British Contribution*, 1313
Planning and the Geography of Great Britain (A, A. L. Caesar), 950
Plant-Animal Complex : Soil- (Dr. T. G. Taylor), 924
Plant Diseases (J. E. van der Plank), *review* by W. C. Moore, 1106
Plant Environment : Physics of (edited by W. R. Van Wijk), *review* by Dr. J. L. Monteith, 444
Plant Leaf Tissue : Some Physical Properties of Interfering Substances associated with the Alkaline Hydrolysis of RNA from (Dr. D. F. Millikan and Dr. E. E. Pickett), 190
Plant Origin and Chick Interferon : Some Similarities between a Viral Inhibitor of (Dr. K. H. Fantes and C. F. O'Neill), 1048
Plant Physiologists : Canadian Society for (Dr. R. G. S. Bidwell), 242
Plant Sources : Specificities of Several Acid Phosphatases from (T. Ikawa et *al.*), 939
Plant Tissue : Heat of Respiration as a Possible Cause of Error in the Estimation by Psychrometric Methods of Water Potential in (Dr. H. D. Barrs), 1136
Plant Tissues : Effects of Growth-regulating Substances on Inulin-storing (Prof. R. L. Wain et *al.*), 504
Plants : Mechanism of Apical Dominance in (G. I. McIntyre), 1190
  Soluble Phosphate in Soil and Uptake by (Dr. A. Wild), 326
  Vegetative Anatomy of (H. G. Burström and C. Odhnoff), *review* by Dr. C. R. Metcalfe, 1005
Plantes Maraichères : Les Maladies des, Vol. I (C. M. Messiaen et R. Lafon), *review* by Dr. R. W. G. Dennis, 1320
Plasma : Multiple Forms of Cholinesterase in Horse (Dr. Y. Oki et *al.*), 605
  Observation of Thomson and Co-operative Scattering of Ruby Laser Light by a (A. W. DeSilva, et *al.*), 1321
  Possible Role of a Phospholipid in the Development of the Slow Muscle Contracting Activity of Human (Dr. Y. Gabr), 765
  Sensitive Double Antibody Immunoassay for Human Growth Hormone in (Dr. D. S. Schalach and Dr. M. L. Parker), 1141
Plasma by Thin-layer and Gas-liquid Radiochromatography : Quantitative Determination of Progesterone in Human (W. P. Collins and Dr. I. F. Sommerville), 836
Plasma Cells in Sites of Inflammation : Origin of (Prof. R. D. Moore and M. D. Schoenberg), 1293
Plasma Column : Effect of Gas Flow on the Properties of a (K. W. Gentle et *al.*), 1369
Plasma Concentrations : Inconstancy of Renal Clearance Values with Changing (Dr. R. B. Con, jun., et *al.*), 143
Plasma Diamine Oxidase Titres of Normal and Pregnant Rats (Dr. Y. Kobayashi), 146
Plasma in a Magnetic Mirror, with Hexpole Stabilizing Fields : Containment of (G. Francis et *al.*), 623
Plasma Magnesium Concentration in Milking Cows : Effect of Applying a Metabolic Harness on the (Dr. H. J. Hendriks), 1306
"Plasma Physics and its Applications in the Field of Thermo-nuclear Reactions and Electrical Power Generation", lectures on, 240
Plasma Waves : The Theory of (Prof. T. H. Stix), *review* by Prof. V. C. A. Ferraro, 224
Plasma and their Relation to 7*S*γ_2-Globulin : Low Molecular Weight γ-Globulins of Urine and (P. Fireman et *al.*), 78
Plasmin-digested Fibrinogen : Inhibition of Thrombin and of Fibrin Polymerization, Two Activities derived from (Z. S. Latallo et *al.*), 1184
Plasmodium berghei, Vincke and Lips, 1948 : Pigment Formation and Nuclear Division in Chloroquine-resistant Malaria Parasites (Dr. W. Peters), 1290
Platinum by the Multipulse Potentio-Dynamic Method : Anion Adsorption on (S. Gilman), 1130
Platt, C. M., et *al.* : Lunar Brightness Distribution at 1·5 mm Wave-length, 960
Platt, Sir Robert appointed chairman of the Medical Research Council's Clinical Research Board, 347
Platt, W. T., and Oyama, Dr. J. : Effect of Deceleration on Rats exposed to Prolonged Centrifugation, 766
Pletscher, Prof. A., et *al.* : Formation of 5-Hydroxytryptophol from Endogenous 5-Hydroxytryptamine by Isolated Blood Platelets, 1281
Plowden Report, 1335
Plutonium in the Marine Environment (K. C. Pillai, Dr. R. C. Smith and Dr. T. R. Folsom), 568
p-n Junctions : Tunnelling-induced Injection in (Prof. M. A. Melehy), 1276
Polarographic Methods : Modern (H. Schmidt and M. von Stackelberg), *review* by J. F. C. Tyler, 1212
Poliovirus-infected Tissue-culture Cells using the 1-Benzyl, 1-Pentyl and 1-Isopropyl Derivatives of 2-(α-Hydroxybenzyl)-benzimidazole : Protection of (Dr. D. G. O'Sullivan, D. Pantic and A. K. Wallis), 433
Political and Economic Planning, annual report, 697
Pollen Extracts Active in Non-sensitized Mice : Permeability Factor in (Prof. L. S. Kind et *al.*), 1390
Polley, Dr. E. H., et *al.* : Effect of Snake Venom and Endotoxin on Cortical Electrical Activity, 1387
Polley, M. J., and Mollison, Prof. P. L. : Uptake of γ-Globulin and Complement by Red Cells exposed to Serum at Low Ionic Strength, 535
Pollock, D. K., et *al.* (edited by) : Optical Processing of Information, *review* by Prof. D. Gabor, 905
Polonium : Incidence and Possible Significance of Inhaled or Ingested (Sir Ernest Marsden), 230
Polydeoxyribonucleotides : Sequence Specificity in Synthetic (Dr. D. Cohen and G. R. Banks), 184
Polyene Antibiotics, with Univalent Cations : Increase of the Effectiveness of (Dr. I. Horváth and I. Koczka), 1305
Polyfunctional Reactant by a Competitive 'Ligandee' : Theory of the *p*H-stat Titration of a (Dr. S. Katz), 858
Polygenes : Balanced Combinations of (Dr. W. Scharloo), 102 ; (Dr. A. Robertson), 102 ; (Prof. J. M. Thoday and J. B. Gibson), 102
Polymorph of Oxamide : A New (J. R. Lehr and Dr. E. H. Brown), 1168
Polymorphism in the Serum Proteins of the Reindeer (Dr. M. Brænd), 674
Polymorphism of Zinc-α_2-Human Glycoprotein (Prof. K. Schmid and S. Takahashi), 407
Polymyxin *B* : Antibacterial Interaction between Bromthymol Blue and (Dr. F. D. Crisley), 211
Polyoma-induced Cellular Antigen(s) in Hybrid Cells : Expression of (Dr. V. Defendi, Dr. B. Ephrussi and Dr. H. Koprowski), 495
Polyoma Viruses : Artificial Heterogenization of Tumours by means of Herpes Simplex and (V. P. Hamburg and Dr. G. J. Svet-Moldavsky), 772
Polypeptide Chains in the Reticulocyte Cell-free System : Initiation of (Dr. J. O. Bishop), 40
Polypeptides : Metabolism of Isomeric Synthetic (Dr. T. J. Gill, III, et *al.*), 644
Polypeptides and Proteins : Fluoroketone Hydrates : Helix-breaking Solvents for (Dr. R. Longworth), 295
Pomeranz, Y., and Mamaril, F. P. : Effect of *N*-Ethylmaleimide on the Starch-liquefying Enzyme from Soy-flour, 863
Ponnamperuma, Dr. C., and Kirk, P. : Synthesis of Deoxyadenosine under Simulated Primitive Earth Conditions, 400
Ponnamperuma, Dr. C., and Woeller, F. : Differences in the Character of C_6 to C_9 Hydrocarbons from Gaseous Methane in Low-Frequency Electric Discharges, 272
Pool, Dr. J. G., et *al.* : High-potency Antihæmophilic Factor Concentrate prepared from Cryoglobulin Precipitate, 312
Pool, W. R., and Lipner, Prof. H. : Inhibition of Ovulation in the Rabbit by Actinomycin *D*, 1385
Pool, W. A. (edited by) : Veterinary Annual 1963/64, fifth year, *review* by G. Lapage, 1212
Popliteal Lymph Node of the Rabbit : Distribution of Intravenously Administered Saccharated Iron Oxide in the (D. W. Menzies and G. B. Ryan), 309
Popliteal and Cubital Fossæ : Extension of Mammary Glands to the (Dr. M. Hirata-Hibi), 1398
Popularizing Science (A. V. S. de Reuck), 340
Populations : Malaria Antibody Content of Gamma$_2$-7*S* Globulin in Tropical (Dr. C. C. Curtain et *al.*), 1366
Porous Electron Emitters (Dr. R. Dewsberry), 746
Porous Membranes : Separation of Hydrocarbon Liquids by Flow under Pressure through (Dr. S. Sourirajan), 1348
Porrazzi, L. Coscia, et *al.* : Deoxycorticosterone Acetate and Experimental Atherosclerosis in Cholesterol-fed Rabbits, 252
Portela, Prof. A., et *al.* : Acetylcholine Receptors in Muscle Membrane, 1179
  Potassium Effects of Cæsium-Choline Interactions in Muscle Membrane, 1071
Possible Interpretation of the Fast Regular Fading Observed on Satellite Transmissions (Dr. L. Liszka), 178
Post Office Radio Services : Mr. H. G. Lillicrap appointed director, 815
Potassium-Argon Ages of Chondrites : Possible Correlation between Classifications and (K. Keil), 511
Potassium-Argon Ages of Slates and their Geological Significance (C. T. Harper), 468
Potassium Content of Various Regions of the Brain of the Cat : Effect of Intraventricularly Injected Anticerebral Antibodies on the Histamine-like Substance and (Dr. L. Mihailović et *al.*), 763
Potassium Effects on Cæsium-Choline Interactions in Muscle Membrane (Prof. A. Portela, J. C. Perez, Prof. P. A. Stewart, M. Luchelli and E. Strajman), 1071
Potassium Permanganate : X-Ray Scattering by Irradiated Single Crystals of (Prof. E. G. Prout and M. E. Brown), 398
Potassium Retention by Brain Slices : L-Cysteine as Inhibitor of (Dr. K. D. Neame), 1067
Potato Blight, 1843–46 : Emergence of (P. M. Austin Bourke), 805
Potatoes : Experimental Production of Buds on the Roots of (Dr. H. W. Howard), 1303
Poulton, E. C., et *al.* : Falling Efficiency at Sorting Cards during Acclimatization at 19,000 ft., 436
"Powder Technology", course of instruction, 819
Power, Dr. D. M., et *al.* : Effects of Inositol-deficiency on Yeast with Particular Reference to Chemical Composition of the Cell and of the Cell Wall, 250
Power : Research and Development for, 816
"Practical Noise Control", short course, 578
Prask, Lt. H. J., et *al.* : Inadequacy of Thermal Initiation Theory in Interpreting the Results of Fission Fragment Irradiation of Explosives at Elevated Temperatures, 473
Pregnancy : Blood Salicylate during (B. Lessel and Dr. E. E. Cliffe), 304
Pregnane-3(alpha), 20(beta)-diol : Production of Unconjugated Hyperbilirubinæmia in Full-term New-born Infants following Administration of (Dr. I. M. Arias and Dr. L. M. Gartner), 1292
Pregnant Rats : Plasma Diamine Oxidase Titres of Normal and (Dr. Y. Kobayashi), 146
Preparation of Spherical Caps for Use on Terrestrial Globes in Investigations of Palæomagnetism and Continental Drift (Prof. J. Hospers), 397
Presence of Carbonate in a Low-density Fraction of Diaphyseal Bone (Dr. L. Richelle and N. Quinaux), 84
Preservation of Rural England, annual report 1963–64, 1340
Preservation of Rural England—Sheffield and Peak District Branch, annual report, 919
Pressure Calibration : Load Discontinuity Method for (J. Lees), 965
Preston, Prof. R. D. : Atlas of Electron Microscopy, *review*, 1103
Price : Dr. A. Grenfell : The Western Invasions of the Pacific and its Continents, *review* by Prof. R. Calder, 560
Price, Derek J. De Solla : Little Science, Big Science, *review* by Prof. J. D. Bernal, 678
Pridham, Dr. J. B. : Biosynthetic Pathways in Higher Plants, 355
Priestley, R., et *al.* : Further Uses of Electronically Scanned Sonar in the Investigation of Behaviour of Fish, 588
Principles of Angiosperm Taxonomy (Dr. P. H. Davis and Dr. V. H. Heywood), *review* by Prof. J. Heslop-Harrison, 333
Pringsheim : Selected Papers of Ernst Georg (edited by Prof. C. B. van Niel), *review* by Dr. S. T. Cowan, 909
Prinsloo, H. E., and Coetzee, Prof. J. N. : Host-range of Temperature *Serratia marcescens* Bacteriophages, 211
Prior, K., and Arridge, R. G. C. : Cooling Time of Silica Fibres, 386
Probabilistic Similarity Index (Dr. D. W. Goodall), 1098

Problem Solving : Evoked Responses to Numerical and Non-numerical visual Stimuli while (Dr. R. M. Chapman and H. R. Bragdon), 1155
Problems of Leisure, 1
Problems of Statecraft and the Civil Service, 555
Procavicola colobi : Mallophaga on Catarrhine Monkeys : *Colobus guereza*, a Natural Host of (Dr. H. J. Kuhn and H. W. Ludwig), 424
Proceedings of the Royal Society of New Zealand, 91, Part 1, 461
Proceedings of the Symposium on Electron and Vacuum Physics, Hungary, 1962 (chief editor : Ernö Winter), *review* by J. Yarwood, 336
Process of Evolution (P. R. Erhlich and R. W. Holm), *review* by Dr. B. S. Cox, 1208
Production by X-rays of Petite Colonies in Yeast and their Radiosensitivity (Dr. H. Laser), 314
Production of *SV*-40 Complement-fixing Antigen (Dr. K. R. Schell), 417
Progesterone in Human Plasma by Thin-layer and Gas-liquid Radiochromatography : Quantitative Determination of (W. P. Collins and Dr. I. F. Sommerville), 836
Progesterone on Activity of Human Myometrial Adenosine Triphosphatase : Inhibitory Effect of (Dr. D. Kumar, P. R. Adams and A. C. Barnes), 83
Progress in Allergy, Vol. 7 (edited by Paul Kallós and Byron H. Waksman), *review* by Dr. D. C. Dumonde, 1105
Progress in Biophysics and Molecular Biology (edited by J. A. V. Butler, Dr. H. E. Huxley and Prof. R. E. Zirkle), Vol. 13, *review* by Dr. J. T. Finch, 557
Progress in Brain Research, Vols. 1–3, *review* by Lord Brain, 3
Progress in Ceramic Science, Vol. 3 (edited by Dr. J. E. Burke), *review* by Dr. N. F. Astbury, 804
Progress in Chemical Toxicology, Vol. 1 (edited by Abraham Stolman), *review* by Dr. H. V. Street, 562
Progress in Nuclear Physics, Vol. 9 (edited by Prof. O. R. Frisch), *review* by G. M. Lewis, 1003
Progress in Nucleic Acid Research, Vols. 1 and 2, (edited by J. N. Davidson and W. E. Cohn), *review* by Dr. S. Brenner, 1004
Progress in Oceanography, Vol. 1 (edited by Dr. M. Sears), *review* by Dr. J. P. Riley, 1317
Progress in Semiconductors, Vol. 7 (edited by Alan F. Gibson and Prof. R. E. Burgess), *review* by Dr. J. R. Tillman, 337
Progressive Desilication of Basic Hornfelses (Dr. P. A. Floyd), 510
Prokop-Schneider, Mrs. B., *et al.* : Rhythmic Alternations in the Rate of Synthesis and the Composition of Rapidly Labelled Ribonucleic Acid during the Synchronous Growth of Bacteria, 479
Proliferation of Transferred Spleen Cells after Antigenic Challenge (Dr. M. J. Cohen and Dr. E. P. Cohen), 418
Promotion of Cell Division in Tissue Cultures by Gibberellic Acid (J. Digby, T. H. Thomas and Prof. P. F. Wareing), 547
Propagation of Radio Waves at Frequencies below 300 kc/s (edited by W. T. Blackband), *review* by J. A. Ratcliffe, 1209
Propagation of Stress Pulses across a Liquid-Steel Boundary (Dr. D. H. Trevena), 291
Propane : Nitrous Oxide as a Scavenger for Electrons in the Radiolysis of (Dr. G. R. A. Johnson and J. M. Warman), 73
Properties, Some, of Differentially Centrifuged Particulate Fractions from Chloroplasts (J. A. Gross, M. J. Becker and A. M. Shefner), 1263
Pros and Cons of International Research Centres, 454
Prostaglandins : Enzymatic Conversion of All-*cis*-Polyunsaturated Fatty Acids into (D. A. van Dorp *et al.*), 839
Protein Antigen : Immunological Paralysis induced in Adult Rabbits by Small Amounts of a (Dr. D. W. Dresser and Dr. G. Gowland), 733
Protein Components of Amyloid (T. J. Muckle), 773
Protein Contents in a Rapidly Differentiating System, the Rat Tapeworm (*Hymenolepis diminuta*) : DNA, PNA and (Dr. T. W. Lee and Prof. J. W. Campbell), 661
Protein Evolution to Tertiary Structure : Relation of (Dr. C. J. Epstein), 1350
Protein Factor promoting Contraction of Actomysin : A New (Prof. S. Ebashi, F. Ebashi and K. Maruyama), 645
Protein Fraction from Wool Keratin : Selective Extraction of a (R. A. Dedeurwaerder *et al.*), 48
Protein in Cell-free Systems from *B. subtillis* : Action of Rifamycin on Incorporation of Amino-acids into (L. Frontali *et al.*), 84
Protein in the Lens : A Cold Precipitable (Dr. S. Zigman and Dr. S. Lerman), 662
Protein Metabolism in Different Mammals : Relationship of Liver Composition to Intensity of (Dr. H. N. Munro and Dr. E. D. Downie), 603
Protein Solutions : Concentrating (Dr. C. Curtain), 1380
Protein Synthesis : Hormones, Amino-acid Transport and (Dr. S. Segal), 17
Protein Synthesis and Turn-over in Cultured Plant Tissue : Sources of Carbon for Synthesis and the Fate of the Protein Breakdown Products (Dr. R. G. S. Bidwell, Dr. R. A. Barr and Prof. F. C. Steward), 367
Proteinoids : Catalytic Decomposition of Glucose in Aqueous Solution by Thermal (Prof. S. W. Fox and Dr. G. Krampitz), 1362
Proteins : Energy Transfer in (L. Augenstein and J. Nag-Chaudhuri), 1145
  Fluoroketone Hydrates : Helix-breaking Solvents for Polypeptides and (Dr. R. Longworth), 295
  New Chromophoric Reagents for Labelling the Thiol Groups of (S. F. Chang and Prof. I. E. Liener), 1065
  Use of Simple Gel-diffusion Techniques to Assign Antigenic Markers to Native (Prof. I. Finger), 1035
Proteins labelled with Iodine-131 from Rat and Rabbit Livers : Distribution and Fate of Soluble (Dr. V. Bocci), 888
Proton Magnetic Relaxation Times of Aqueous Tetra Alkyl Ammonium Halide Solutions (Prof. C. S. Danyluk and E. S. Gore), 748
Prout, Prof. E. G., and Brown, M. E. : X-Ray Scattering by Irradiated Single Crystals of Potassium Permanganate, 398
Prout, Prof. E. G., and Moore, D. J. : Thermal Decomposition of Barium Azide, 860
Prouvost-Danon, Dr. A., and Queiroz da Cruz, M. : Effect of Excess of Antigen on the Active Anaphylactic Reaction *in vitro*, 876
Providence Strains : Transmission of Colicinogeny to (Prof. J. N. Coetzee), 897
Pscheidt, Dr. G. R., et *al.* : Variations of Urinary Creatinine and its Correlation to Tryptamine Excretion in Schizophrenic Patients, 1198
Pseudocholinesterases (Acylcholine-Acylhydrolase, *EC* 3.1.1.8) in *Macaca mulatta* (*rhesus*) and *Cercopithecus aethiops* : Activities of (Dr. H. W. Goedde and V. Riedel), 1405
Pseudococcus citri : Base Ratios in DNA in Male and Female (Dr. M. W. Loewus. et *al.*), 104
Psychological Stress in the Specific Cardiotoxicity of Drugs : Influence of (Prof. . A. Marino), 1289
Psychologie Expérimentale : Traite de (Sous la direction de Paul Fraisse et Jean Piaget), Vols. 1, 2, 5 and 6, *review* by Prof. O. L. Zangwill, 109
Psychology : Readings in (edited by Prof. John Cohen), *review* by Dr. D. W. Forrest, 1318
Psychrometric Methods of Water Potential in Plant Tissue : Heat of Respiration as a Possible Cause of Error in the Estimation by (Dr. H. D. Barrs), 1136
Public Libraries and Museums Bill, 1335
Purdom, Dr. C. E., and Bridges, Dr. B. A. : Effect of Sulphydryl Reagents on the Frequency of X-ray-induced Autosomal Rescessive Lethal Mutations in *Drosophila melanogaster*, 419
Purification of Pinguinain by Gel Filtration (Dr. E. Toro-Goyco and M. Matos), 82
Purine- and Pyrimidine-specific Antibodies : Precipitation with Denatured Deoxyribonucleic Acid (Prof. S. M. Beiser, Prof. S. W. Tanenbaum and (Prof. B. F. Erlanger), 1381
Purkinje Cells by the Climbing Fibres : Excitation by Cerebellar (Sir John Eccles et *al.*), 245
Purnell, Dr. J. H. : La Chromatographie, second edition, *review*, 686
Puromycin : Nucleolus-like Inclusions in the Cytoplasm of HeLa Cells treated with (Dr. G. P. Studzinski), 883
Puromycin on Insulin and Epinephrine Control of Fatty Acid Release from Adipose Tissue : Effect of Aminonucleoside and (Dr. A. Korner and Dr. M. S. Raben), 1287
Purnell, Dr. J. H., et *al.* : Liquid-gas Interface Effects in Gas Chromatography, 1279
Pyridoxal-β-Cyanoalanine Relation in the Rat (Dr. C. Ressler, Mrs. J. Nelson and Dr. M. Pfeffer), 1286
Pyridozine Deficiency in the Rat produced by D-Penicillamine (A. M. Asatoor), 1382
Pyrimidine-specific Antibodies : Purine- and Precipitation with Denatured Deoxyribonucleic Acid (Prof. S. M. Beiser et *al.*), 1381
Pyrolytic Graphite and its Variation due to Non-Alignment of the Crystallites : Thermal Expansion of (R. H. Knibbs and I. B. Mason), 58
Pyrophosphate Content and Oxytetracycline Labelling of Bone Salt : Relationship between (Dr. K. H. Ibsen and Dr. M. R. Urist), 761

QUAGLINO, D., et *al.* : Cytology and Cytochemistry of Acute Leukæmias, *review* by Dr. M. H. Salaman, 683
Quail : Effect of Photoperiod on Cyclic Patterns of Body Temperature in the (A. E. Woodard and F. B. Mather), 422
Quail, American Bobwhite (*Colinus virginianus*) : Synchronization of Hatching in (M. A. Vince), 1192
Quantitative Analysis of Drugs (Dr. D. C. Garratt), third edition, *review* by A. Holbrook, 334
Quantitative Determination of Progesterone in Human Plasma by Thin-layer and Gas-liquid Radiochromatography (W. P. Collins and Dr. I. F. Sommerville), 836
Quantitative Inorganic Analysis : Methods of (K. Kodama), *review* by A. D. Wilson, 559
Quantitative Relations between Doses of Chemical Protective Agents and Doses of X-irradiation (Prof. R. Koch and I. Seiter), 984
Quantity Production of Synchronized Mammalian Cells in Suspension Culture (D. F. Petersen and E. C. Anderson), 642
Quantum Mechanics : Foundations of (Prof. P. A. M. Dirac), 115
Quantum Mechanics Exclude Life, Does ? (Prof. P. T. Landsberg), 928
Quarterly Review of Scientific Publications (No. 1, 1964), 1017
Quaternary Alkaloid from *Croton turumiquirensis*, Stayerm. (R. H. Burnell and D. D. Casa), 296
Queen's College, Dundee : Baxter chair of applied Mathematics, 696
Queen's University of Belfast : Appointments, 700
Queiroz da Cruz, M., and Prouvost-Danon, Dr. A. : Effect of Excess of Antigen on the Active Anaphylactic Reaction *in vitro*, 876
Quigley, M. J. S., and Haslam, C. G. T. : Association of the Galatic Radio Spur with the Scorpio X-ray Source, 1272
Quinacillin : A Comparison with other Pencillinase-resistant Pencillins (Dr. J. T. Smith, Dr. J. M. T. Hamilton-Miller and Prof. R. Knox), 1148
Quinaux, N., and Richelle, Dr. L. : Presence of Carbonate in a Low-density Fraction of Diaphyseal Bone, 84

RABEN, Dr. M. S., and Korner, Dr. A. : Effect of Aminonucleoside and Puromycin on Insulin and Epinephrine Control of Fatty Acid Release from Adipose Tissue, 1287
Rabinowitch, Eugene : The Dawn of a New Age, *review* by Prof. D. Gabor, 800
Radczenko, G. P., et *al.* (edited by) : Fundamentals of Palæontology, Vol. 15, *review* by Dr. W. G. Chaloner, 685
Radda, Dr. G. K. : Electronic Effects and L-Amino-acid Oxidase Specificity, 936
Radford, Dr. C. A. Ralegh : History and Archæology, 951
Radiation : Reduction in Rate of Growth of Hair in Mice as an Indicator of Exposure to Chronic Low Dosage Ionizing (D. C. Chow et *al.*), 847
Radiation Chemical Reactions in Deoxygenated Peptide Solutions (J. Liebster and J. Kopoldová), 636
Radiation Effect on Ascitic Tumour Cells by Pharmacological Agents injected intravenously : Modification of the (Dr. J. N. Correa and Dr. J. Robert Andrews), 200
Radiation Inactivation of the Immunological and Biological Activities of Human Chorionic Gonadotropin (Dr. W. E. Paul and Dr. W. D. Odell), 979
Radiation-induced Changes in Metabolism of Thymine in Rat (T. H. Bates, C. I. Smith and Dr. Hylton Smith), 843
Radiation-induced Mutations in *Escherichia coli* : Segregation of (Dr. R. J. Munson and Dr. B. A. Bridges), 270
Radiation Injury (Dr. P. J. Lindop), 587
Radiation Nephritis, 1017
Radiation Resistance and Deoxyribonucleic Acid Base Composition of *Micrococcus radiodurans* (Dr. B. E. B. Moseley and Dr. A. H. Schein), 1298
Radiative Detonation Model for the Development of a Laser-induced Spark in Air (S. A. Ramsden and P. Savic), 1217
Radiative Transfer : Treatise on (V. V. Sobolev), *review* by Dr. I. W. Busbridge, 112
Radical Reactions : Isotope Effect in (Dr. J. R. Majer et *al.*), 294
Radio : Balthazar van der Pol Gold Medal for Scientific (Dr. R. L. Smith-Rose), 241
Radioactive Antigens : Use of Antibodies on an Insoluble Support for Specific Detection of (A. E. Gurvich and G. I. Drizlikh), 648
Radioactive Fall-out, 1962–64 : Increase in the Cæsium-137 Content of Man due to (Dr. J. Rundo and D. Newton), 537
Radioactive Isotope Dilution Analysis, 1122
Radioactive Labelling : Recovery of the Viral Antigen in a Cell by means of Double (Prof. V. M. Zhdanov et *al.*), 670
Radioactive Measurements : Rate of Accumulation of Snow at the South Pole as Determined by (E. Picciotto et *al.*), 393
Radioactive Particles and Gases : Inhaled (Dr. C. N. Davies), 352
Radioactivity, Long-life, in Occasional Thyroids (Prof. L. Van Middlesworth), 199
Radioactivity of Plankton: Alpha- (R. D. Cherry), 139

Radio Astronomy and Space Science : Allocation of Frequencies for (Dr. R. L. Smith-Rose), Substance of a paper presented at the Seventh Plenary Meeting of the International Committee on Space Research (COSPAR), 1964, 7
Radiocæsium from Beef : Removal of (Prof. G. D. Gernon, jun.), 1189
Radiocalcium in Tetracycline-treated Rats : Bone Growth and Uptake of (Dr. R. C. Likins and (G. A. Pakis), 1069
Radiochromatography : Quantitative Determination of Progesterone in Human Plasma by Thin-layer and Gas-liquid (W. P. Collins and Dr. I. F. Sommerville), 836
Radio Emission : Pattern in the Large-scale Distribution of Galactic Polarized (D. S. Mathewson and D. K. Milne), 1273
Radio Engineers : Abstracts of Papers published in the Journal of the British Institution of 1952–1963, 23
Radioisotopes in Hydrology, 1122
Radiological Protection Service ; Regional Centres, 1016
Radiolysis of Organic Liquids : Formation of Triplet States of Solutes in the (Prof. F. S. Dainton et *al*.), 1050
"Radio Meteorology", 1964 World Conference, 351
Radio Noise Fields in the Tropics : Lightning Flash Counts and (Dr. O. Ibukun), 66
Radionuclide (D. Kurt Schmeiser), *review* by Dr. E. Glueckauf, 910
Radionuclides of Biological Interest in Pacific Waters : Analyses of (D. Chakravarti et *al*.), 571
Radio Observations of Flare Stars : Simultaneous Photoelectric and (Sir Bernard Lovell and Dr. P. F. Chugainov), 1213
Radio Observations of the Crab Nebula during a Lunar Occultation (B. H. Andrew, N. J. B. A. Branson and D. Wills), 171
Radio-Protection of the Reaction of Cells to Sulphydryl and Disulphide Compounds : Importance for (Prof. Z. M. Bacq and Dr. P. Alexander), 162
Radiosensitivity : Production by X-rays of Petite Colonies in Yeast and their (Dr. H. Laser), 314
Radiosensitivity of a Mammalian Cell Line with Phase of the Growth Cycle : Variations in (H. Madoc-Jones), 983
Radio Sources : Interplanetary Scintillation of Small Diameter (Dr. A. Hewish et *al*.), 1214
Radio Storms, Type I Solar, and the Coronal Magnetic Field : Spectral Evidence on the Origin of (J. P. Wild and A. Tlamicha), 1128
Radio Telescope : Jodrell Bank *Mark* II (Sir Bernard Lovell), 11
Ragge, D. R. : Dissection of the Locust, *review*, 909
  Physiologie, Comportement et Écologie des Acridiens en Rapport avec la Phase (Colloques Internationaux du Centre National de la Recherche Scientifique, No. 114, 1962), *review*, 686
Rahman, A., et *al*. : National Laboratories in India, 582
Rainbow, C. : Chemistry and Biochemistry of Fungi and Yeasts : Proceedings of the Symposium on the Chemistry and Biochemistry of Fungi and Yeasts, July 1963, *review*, 803
Rainey, Dr. R. C. : Tropical Meteorology in Africa, *review*, 561
Rain Water : Fall-out in London (Dr. R. Wood et *al*.), 617
Rajagopal, N. R., et *al*. : National Laboratories in India, 582
Ralph, Prof. C. L., and McCarthy, R. : Effects of Brain and Corpus Cardiacum Extracts on Hæmolymph Trehalose of the Cockroach, *Periplaneta americana*, 1195
Ralphs, Dr. F. Lincoln : Responsibility and Education, 954
Ramsay Memorial Fellowships Trustees awards for 1964–65, 1228
Ramsden, D., and Watt, D. E. : High Sensitivity Counting Techniques, *review* by Prof. W. E. Burcham, 5
Ramsden, S. A., and Savic, P. : Radiative Detonation Model for the Development of a Laser-induced Spark in Air, 1217
Randall, Sir John, et *al*. : A Single-gene Mutation of *Chlamydomonas reinhardii* Affecting Motility : a Genetic and Electron Microscope Study, 912
Random Variables : Some Properties of (J. C. Koop), 1097
Rao, Dr. W. V. B. Sundara, and Iswaran, Dr. V. : Role of Cobalt in Nitrogen Fixation by *Azotobacter chroococcum* ; 549
Rapkine Memorial Lecture, 920
Rapport, S., and Wright, H. (edited by) : Science : Method and Meaning, *review* by R. Brightman, 685
Rasmussen, Dr. R. E., and Painter, Dr. R. B. : Evidence for Repair of Ultra-violet Damaged Deoxyribonucleic Acid in Cultured Mammalian Cells, 1360
Ratcliffe, J. A. : Propagation of Radio Waves at Frequencies below 300 kc/s, *review*, 1209
  Sun and the Ionosphere, 948
Ratledge, Dr. C. : Relationship between the Products of Aromatic Biosynthesis in *Mycobacterium smegmatis* and *Aerobacter aerogenes*, 428
Rauscher Virus in Cultures of Mouse Kidney Cells : Multiplication of (J. Peries et *al*.), 672
Ravkina, L., et *al*. : Experimental Myopathic Syndrome associated with Pituitary Activation of Thymus, 771
Rawlins, F. I. G. : Edmund Husserl's Theory of Meaning, 680
Raynaud, Prof. M., and Iscaki, S. : Co-precipitating Properties of 3 *S* Fragments derived from Horse Antitoxins, 758
Rea, E. : The Age of Advice, 954
Reaction between Portland Cement Clinker and Water (A. K. Chatterji and T. C. Phatak), 138
Reactor Physics : Manual of Experiments in (edited by Prof. F. A. Valentine), *review* by J. F. Hill, 804
Reading, Dr. H. W. : Activity of the Hexose Monophosphate Shunt in the Normal and Dystrophic Retina, 491
Readings in Psychology (edited by Prof. John Cohen), *review* by Dr. D. W. Forrest, 1318
Reagin Activity in Purified γ_{1A}-Globulin : Direct Demonstration of (J. P. Vaerman, W. Epstein, Prof. H. Fudenberg and K. Ishizaka), 1046
Reappraisal of Treasury Control, 797
"Recent Advances in Activation Analysis", conference on, 24
Receptor of the Melezitose Locus in *Saccharomyces* : Palatinose Element of the (D. S. Hwang and Prof. C. C. Lindegren), 791
Receptors in the Sucker of the Cuttlefish (Prof. P. Graziadei), 384
Reciprocal Activation and Inhibition by Cortical Neurones and Voluntary Movements in Man : Cortical Cell Activity and Muscle Movement (Dr. C.-L. Li and Dr. J. M. Tew, jun.), 264
Recognition of Simple Forms (Prof. P. Meredith), 1370 ; (Dr. G. E. Ham), 1370
Reconstruction of the Continents for the Upper Palæozoic from Palæomagnetic Data (Dr. K. M. Creer), 1115
Recordings from Satellite *Alouette I* (N. M. Brice and R. L. Smith), 926 ; (N. M. Brice, R. L. Smith), J. S. Belrose and R. E. Barrington), 926
Recovery following X-irradiation of Synchronized Chinese Hamster Cells (Dr. W. K. Sinclair and R. A. Morton), 247
Red Cells exposed to Serum at Low Inoic Strength : Uptake of γ-Globulin and Complement by (Prof. P. L. Mollison and M. J. Polley), 535
Red Cells from Turkeys : Hæmagglutination Reaction with Vaccinia Virus : Agglutinability of (Dr. N. S. Datt), 1406
Red Cells of Immune Rabbit 7*S* Antibody and its Sub-units : Combination with (Dr. C. L. Greenbury, D. H. Moore and Dr. L. A. C. Nunn), 1147
Redox Cleavage of S—S Linkage in Diaryl and Cyclic Alkyl Disulphides (C. H. Wang), 75
Rees, E. P., and Trevena, Dr. D. H. : Effect of Precompression on the Critical Tension of Liquids, 396
Reflectance Technique : Infra-red Spectra of Aqueous Solutions by the Attenuated Total (Dr. J. D. S. Goulden and D. J. Manning), 403
Reflex Responses in Man Evoked by Gamma Efferent Activation (J. Thorne), 612
Rege, Mrs. V. P., et *al*. : Isolation of Serologically Active Fucose-containing Oligosaccharides from Human Blood-group H Substance, 360
Registrar General's Quarterly Return for England and Wales, ended 31st March, 1964, 1122
Reichelderfer, Dr. F. W. : Awarded the International Meteorological Organization Prize for 1964, 125
Reichle, R. E., et *al*. : *Hypomyces* Stage of *Fusarium solani f. pisi*, 664
Reid, D. A. : The Mushroom Hunter's Field Guide, *review*, 1320
Reid, E., and Turner, M. K. : Anomalous Effect of Ethionine on Ribonucleic Acid Synthesis, 1174
Reid, jun., J. L. : Evidence of a South Equatorial Counter-current in the Atlantic Ocean in July 1963, 182
Reid, W. E., and Kruger, Dr. J. : Optical Investigations of Film Formation and Removal on Gold Anodes in Acidic Oxalate Solutions, 402
Reif, Prof. A. E., and Allen, Mrs. J. M. V. : Immunological Distinction of *AKR* Thymocytes, 886
Reilley, Charles N. (edited by) : Advances in Analytical Chemistry and Instrumentation, Vol. 2, *review* by R. J. Mesley, 442
Reilly, R. W., et *al*. : Effect of Œstradiol on Bone Marrow Transplantation in Lethally Irradiated Mice, 265
  Removal and Dissociation of Epithelial Cells from the Rodent Gastrointestinal Tract, 319
Reilly, T. A., and Matthews, Dr. D. H. : Disappointing Interim Palæomagnetic Results from the Seychelles, 1160
Reindeer : Polymorphism in the Serum Proteins of the (Dr. M. Brænd), 674
Reith Lectures, 1963 : *A University in the Making* (Dr. A. E. Sloman), 107
Rejection of Isogeneic Murine Skin Grafts following Exposure to Allogeneic Ribonucleic Acid (R. D. Guttmann, E. D. Kraus and M. F. Dolan), 196
"Relation of Measurements of Radioactive Contamination in the Working Environment to Personal Exposure", symposium on, 1124
Relationship between the *H* Chain Groups of 7*S* γ-Globulin and the Gm System (Dr. H. G. Kunkel, J. C. Allen, H. M. Grey, L. Martensson and Prof. R Grubb), 413
Relativity : Bearing of Recent Experiments on the Special and General Theories of (Dr. R. C. Jennison), 395 ; (Dr. L. Essen), 395
Relevance of Biochemical Taxonomy to the Problem of Lathyrism (Dr. E. A. Bell), 378
Removal and Dissociation of Epithelial Cells from the Rodent Gastrointestinal Tract (D. S. Harrer, Dr. B. K. Stern and Dr. R. W. Reilly), 319
Renal Clearance Values with Changing Plasma Concentrations : Inconstancy of (Dr. R. B. Conn, jun., et *al*.), 143
Renal Immunofluorescence in *NZB*/*NZW* Mice (I. Aarons), 1080
Rennert, O. M., and Anker, H. S. : Effect of 5′,5′,5′-Trifluoroleucine on a Number of Mouse Leukæmias, 1256
Renshaw, G. D., et *al*. : Production of Dislocation Etch Pits on Calcite using Optically Active Etchants, 72
Renshaw Cells : Nicotinic and Muscarinic Receptors of (Dr. D. R. Curtis and R. W. Ryall), 652
Reorganization of Civil Science in Britain, 574
Repetti, R. V., and Leonard, Prof. E. F. : Segré-Silberberg Annulus Formation : A Possible Explanation, 1346
Report on the Industrial Fund for the Advancement of Scientific Education in Schools (Sir Graham Savage), 27
Report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Department of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds, 1962–63, 244
Reproductive Ability by Homologous Testes-DNA of Rats irradiated during the Infantile Period : Recovery of (Dr. N. Savković), 1297
Reproductive Capacity of Mammalian Cells : A Comparison of Effects of some, Chemotherapeutic Agents and those of X-rays on the (Dr. R. J. Berry) 1150
Research at the Home Office Police Research and Planning Branch, 1016
Research Centres : Pros and Cons of International, 454
Research Expenditure and Industry (Prof. F. C. Thompson), 466
Research in Textiles, Colour Chemistry and Dyeing, 244
Research into Research (S. Gustavsson), 26
Research and Education in Physics, international seminar, 128
Resistance against Carcinomas of the Skin induced by Dimethylbenzanthracene (DMBA) in Mice of the Strain XVII/*Bln* (G. Pasternak, Prof. A. Graffi, F. Hoffman and K. H. Horn), 307
Resistance Inequalities (Dr. S. Simons), 1059
Resistance of Infectious RNA and Transforming DNA to Iodine which inactivates f_2 Phage and Cells (Prof. Y.-C. Hsu), 152
Resistance to Warfarin in the Common Rat (M. Lund), 778
Resnik, R. A. : Interaction of Mercuric Ion with Hæmoglobin, 880
Response, An Unlearned, altered by Section of Chiasma and Corpus Callosum in Monkeys : Optokinetic Nystagmus (Dr. T. Pasik and Dr. P. Pasik), 609
Response of a New Hibernator (*Citellus variegatus*) to Controlled Environments (E. T. Pengelley), 892
Responsibility and Education (Dr. F. Lincoln Ralphs), 954
Ressler, Dr. C., et *al*. : Pyridoxal-β-Cyanoalanine Relation in the Rat ; 1286
Resurgence of Interest in the Observational Sciences (Sir Graham Sutton), 955
Reticulocyte Cell-free System : Initiation of Polypeptide Chains in the (Dr. J. O. Bishop), 40
Retina : Activity of the Hexose Monophosphate Shunt in the Normal and Dystrophic (Dr. H. W. Reading), 491
Retinæ : Periodicity of Absorption Properties in Pigments based on Vitamin A_2 from Fish (Dr. C. D. B. Bridges), 303
Retinal Image : Perception of Pattern and Colour in the Stabilized (G. W. Beeler et *al*.), 1200
Retinal Pigments of Two Fishes : Effect of Season and Environment on the (Dr. C. D. B. Bridges), 191
Retino-hypothalamic Connexions in Cetacea (Prof. M. S. Jacobs and Dr. P. J. Morgane), 778
Retroactive Interference in Short-term Memory (Dr. H. C. A. Dale), 1408
Révész, L., and Littbrand, Bo. : Recovery from X-ray Injury and the Effect of Oxygen, 889
  Variation of the Relative Sensitivity of Closely Related Neoplastic Cell Lines Irradiated in Culture in the Presence or Absence of Oxygen, 742
Rheid and Rigid Rotations (E. S. O'Driscoll), 832
Rhizome Development in *Agropyron repens* L. Beauv. : Influence of Nitrogen Nutrition on Bud and (G. L. McIntyre), 1084

Rhodium-102 and Manganese-54 in Surface Air : Concentrations of Cæsium-137 (P. F. Gustafson *et al.*), 470
Rhodnius prolixus Stål. : Some Effects of Decapitation on Metabolism in (G. C. Coles), 323
Ribonuclease : an Example of Complementary Inhibition : Combination Chemotherapy with Actinomycin D and (Prof. A. C. Sartorelli), 877
Ribonucleic Acid : Rejection of Isogeneic Murine Skin Grafts following Exposure to Allogeneic (R. D. Guttman *et al.*), 196
Ribonucleic Acid Base Composition : Acid-labile Ribose as an Indicator of (D. I. Eddy), 186
Ribonucleic Acid Composition to Growth Rate and Dormancy in *Bacillus subtilis* : Relation of (Prof. R. H. Doi and R. T. Igarashi), 1092
Ribonucleic Acid during the Synchronous Growth of Bacteria : Rhythmic Alternations in the Rate of Synthesis and the Composition of Rapidly Labelled (Dr. R. Rudner *et al.*), 479
Ribonucleic Acid extracted from Calf's Spleen : Effect on Leukæmic Cells of (Prof. S. Esposito), 1078
RNA from Plant Leaf Tissue : Some Physical Properties of Interfering Substances associated with the Alkaline Hydrolysis of (Dr. D. F. Millikan and Dr. E. E. Pickett), 190
Ribonucleic Acid on the Differentiation of Hæmatopoietic Tissue in Chick Embryos : Influence of Extraneous (P. Malpoix), 520
RNA on Vascular Permeability in the Rat: Effect of (D. A. Willoughby, M. N. I. Walters and Prof. W. G. Spector), 882
RNA Polymerase from Rat Testis : Isolation of a Soluble (P. Ballard and Prof. H. G. Williams-Ashman), 150
Ribonucleic Acid Synthesis : An Anomalous Effect of Ethionine on (M. K. Turner and E. Reid), 1174
  Effect of γ-Radiation on Deoxynucleoprotein acting as a Primer in (Prof. J. J. Weiss and Dr. C. M. Wheeler), 291
RNA and Transforming DNA to Iodine which Inactivates f_2 Phage and Cells : Resistance of Infectious (Prof. Y.-C. Hsu), 152
Ribonucleic Acids : Fractionation of (Dr. R. Barber and Dr. A. S. Jones), 45
Ribonucleoprotein Metabolism : Cytochemical Investigations of Deoxyribonucleic Acid-mediated Control of (Dr. R. Love *et al.*), 1384
Rice-Evans, Dr. P., and Barrett, S. M. : Sensitivity of Hands to Visible Light, 993
Richards, Prof. E. J. : A Course of Lectures on the Theory of Sound, *review*, 560
Richards, E. W. T., and Ridgeley, A. : Empirical Level Rule for Spectroscopic Terms approximating to *LS*-Coupling, 1277
Richards, L. A., *et al.* : Fall-out in London Rain Water, 617
Richards, W., *et al.* : Permeability Factor in Pollen Extracts Active in Non-sensitized Mice, 1390
Richelle, Dr. L., and Quinaux, N. : Presence of Carbonate in a Low-density Fraction of Diaphyseal Bone, 84
Riddihough, R. P. : Magnetic Survey off the North Coast of Ireland, 747
Rideal, Sir Eric : Fuel Cells, *review*, 1315
Ridgeley, A., and Richards, E. W. T. : Empirical Level Rule for Spectroscopic Terms approximating to *LS*-Coupling, 1277
Ridley, J. D., and Cockayne, Dr. B. : Scheelite Structures : Single Crystal Growth and Transmission Data, 1054
Riedel, V., and Goedde, Dr. H. W. : Activities of Pseudocholinesterases (Acylcholine-Acylhydrolase, *EC* 3.1.1.8) in *Macaca mulatta* (*rhesus*) and *Cercopithecus aethiops*, 1405
Rieder, Dr. R. F., and Weatherall, Dr. D. J. : Variation in the Electrophoretic Pattern of Human Erythrocyte Carbonic Anhydrase, 1364
Ries, jun., Dr. H. E., and Walker, D. C. : Effect of the Spreading Solvent on Monolayer Properties, 292
Rifamycin on Incorporation of Amino-acids into Protein in Cell-free Systems from *B. subtilis* : Action of (L. Frontali *et al.*), 84
Rihan, Z. El Baz., *et al.* : Effects of Adenine and Guanine on Hepatic Glucose Release and on the Action of Insulin on the Liver, 1186
Riley, Dr. J. P. : Progress in Oceanography, Vol. 1, *review*, 1317
Riley, Dr. R., and Chapman, V. : Cytological Determination of the Homœology of Chromosomes of *Triticum aestivum*, 156
Ringbom, Anders : Complexation in Analytical Chemistry, *review* by Dr. J. R. Cooke, 559
Ritchie, Prof. H. D., and Shead, G. V. : Concentration of Ammonia in the Gastric Venous Blood of Dogs during Acid Secretion, 1073
Ritman, P., and Loo, Y. H. : New Metabolites of Phenylalanine, 1237
Road : The Trans-Canada Highway, the longest paved road, 239
Robb, Prof. J. C., *et al.* : Isotope Effect in Radical Reactions, 294
Roberts, J. A., and Komesaroff, M. M. : Evidence for Asymmetry of Jupiter's van Allen Belt, 827
Roberts, J. T., *et al.* : Acidophilia of Aortic Elastin in the Child, 195
Roberts, Prof. S., *et al.* : Stimulation of Steroid C-11β Hydroxylase Activity in Adrenal Homogenates by Cyclic 3',5'-Adenosine Monophosphate, 759
Robertson, Dr. A. : Balanced Combinations of Polygenes, 102
Robertson, D. S., *et al.* : Calcium Fluoride : Slip and Polygonization during Crystal Growth, 1376
Robertson, R. N. M. : Southampton Meeting of the British Association for the Advancement of Science, 235
Robinson, B. E., and Anderson, W. M. : Metric to Inch Conversion, 551
Robinson, Dr. J. D., and Green, Dr. J. P. : Presence of Imidazoleacetic Acid Riboside and Ribotide in Rat Tissues, 1178
Robinson, P. M., and Park, Dr. D. : Isolation and Bioassay of a Fungal Morphogen, 988
Robinson, Dr. R. W., *et al.* : Mast Cells and Hyaluronic Acid in the Bovine Endometrium, 730
Rockborn, G., and Gustavsson, I. : Chromosome Abnormality in Three Cases of Lymphatic Leukæmia in Cattle, 990
Roderick, H. R., and Coombs, Dr. M. M. : Carrier-free (7-^{3}H)-Testosterone, 523
Rodriguez, M. P., *et al.* : Unit Cell and Space Group of $Co(thiourea)_4(NO_3)_2$, 513
Rodríguez-Lopez, Dr. M. : Influence of the Inoculum and the Medium on the Growth of *Chlorella pyrenoidosa*, 666
Roe, Dr. F. J. C. : Unusual Forms and Aspects of Cancer in Man, 356
Roeser, W. F., *obituary*, 1224

Rojas, J., *et al.* : Effect of Glucose on Insulin Secretion *in vitro* by Rabbit Pancreas pre-incubated with β-Hydroxybutyrate, 758
Role of DDT-hydroxylation in Resistance (A. Morello), 785
Rolinson, G. N., *et al.* : Development *in vitro* of Bacterial Cross-resistance involving Penicillins, Chloramphenicol and Tetracycline, 548
Romberger, J. A. : Meristems, Growth and Development in Woody Plants, *review* by Prof. C. W. Wardlaw, 562
Roots of Potatoes : Experimental Production of Buds on the (Dr. H. W. Howard), 1303
Roscoe, C., *et al.* : Production of Dislocation Etch Pits on Calcite using Optically Active Etchants, 72
Rosenberg, A., *et al.* : Optical Rotatory Dispersion of Liver Alcohol Dehydrogenase and its Complexes, 755
Rosenberg, Dr. H. : Distribution and Fate of 2-Aminoethylphosphonic Acid in *Tetrahymena*, 299
Rosenberg, Dr. H., *et al.* : Biosynthesis of L-Serine Ethanolamine Phosphodiester, 410
Rosenthal, Dr. H. L., *et al.* : Incorporation of Fall-out Strontium-90 in Deciduous Incisors and Fœtal Bone, 615
Ross, G., *et al.* : Simultaneous Electromagnetic Measurement of Blood Flow in the Major Coronary Arteries, 148
Ross, G. W., *et al.* : Staphylococcal Teichoic Acid Antibody in the Sera of Patients with Burns, 1173
Rossi, Dr. G. B., *et al.* : Deoxycorticosterone Acetate and Experimental Atherosclerosis in Cholesterol-fed Rabbits, 252
  Failure to induce Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs, 416
Roston, Dr. S. : Interaction of Glutathione and Epinephrine within the Human Blood Cell, 1075
Rotation : Gravity and (Dr. R. Capildeo), 175
  Rheid and Rigid (E. S. O'Driscoll), 832
Rotation of the Globular Cluster ω Centauri (Sir Richard Woolley), 961
Rothman, Prof. S., *et al.* : Reduction in Rate of Growth of Hair in Mice as an Indicator of Exposure to Chronic Low Dosage Ionizing Radiation, 847
Rothschild, The Hon. M., and Ford, B. : Maturation and Egg-laying of the Rabbit Flea (*Spilopsyllus cuniculi* Dale) induced by the External Application of Hydrocortisone, 210
Rous Sarcoma Virus : Transformation of Embryonic Human Cells by (Dr. L. Zilber and V. Shevijaghyn), 194
Rous Sarcoma Virus between Cells from Two Inbred Lines of Domestic Fowl : Difference in Susceptibility to Lymphoid Leukosis Virus and (Dr. L. N. Payne and Dr. P. M. Biggs), 1306
Roux, Georges : Ancient Iraq, *review* by T. K. Penniman, 802
Rowbury, Dr. R. J. : Synthesis of Cystathionine and its Control in *Salmonella typhimurium*, 977
Roy, A. K., *et al.* : National Laboratories in India, 582
Royal Botanic Garden, Edinburgh : New Herbarium, Library and Offices, 694
Royal College of Science and Technology, Glasgow : Annual Report, 1962–63, 700
Royal Greenwich Observatory, 918
Royal Society : Expedition to the Solomon Islands, 696
  Foulerton Gift Research Fellowship, 237
  Galileo Celebration, 237
  Research Appointment at Wadham College, Oxford, 237
Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme, tenth annual report, 126
  Bursaries Scheme, 920
Royal Statistical Society : Officers for 1963/64, 24
  Guy Medal in Silver awarded, 24
Royal Veterinary College : Chair of veterinary microbiology, 1121
Rschevkin, S. N. : A Course of Lectures on the Theory of Sound, *review* by Prof. E. J. Richards, 560
Rubber Research Institute of Malaya, 1227
Rubenstein, Dr. M., and Wolff, Dr. S. M. : Suppression of Antibody to Endotoxin with 6-Mercaptopurine : Effect of Antigen Dose, 1390
Rubin, Dr. R. P., and Douglas, Prof. W. W. : Stimulant Action of Barium on the Adrenal Medulla, 305
Ruby Laser Light by a Plasma : Observation of Thomson and Co-operative Scattering of (A. W. DeSilva *et al.*), 1321
Rudin, A., *et al.* : Fracture of Liquids in Shear, 175
Rudner, Dr. R., *et al.* : Rhythmic Alternations in the Rate of Synthesis and the Composition of Rapidly Labelled Ribonucleic Acid during the Synchronous Growth of Bacteria, 479
Ruffie, J., *et al.* : Does a Connexion exist between Blood Group Modifications observed in Leukæmia and Certain Chromosomal Alterations ? 432
Rugby School Natural History Society, ninety-seventh report, 239
Runcorn, Prof. S. K. : *obituary* of Prof. J. Bartels, 814
Rundo, Dr. J., and Newton, D. : Increase in the Cæsium-137 Content of Man due to Radioactive Fall-out, 1962–64, 537
Rusby, Dr. J. S. M. : Underwater Acoustics : Proceedings of an Institute sponsored by the Scientific Affairs Committee of the North Atlantic Treaty Organization, London, 1961, *review*, 1320
Russe, H. P., *et al.* : Effect of Œstradiol on Bone Marrow Transplantation in Lethally Irradiated Mice, 265
Rutgeerts, M. J., *et al.* : Influence of the Injection of a Sucrose Solution on the Properties of Rat-liver Lysosomes, 757
Rutherford, P. P., *et al.* : Effect of Growth-Regulating Substances of Inulin-storing Plant Tissues, 504
Ryall, R. W., and Curtis, Dr. D. R. : Nicotinic and Muscarinic Receptors of Renshaw Cells, 652
Ryan, G. B., *et al.* : Acidophilia of Aortic Elastin in the Child, 195
Ryan, G. B., and Menzies, D. W. : Distribution of Intravenously Administered Saccharated Iron Oxide in the Popliteal Lymph Node of the Rabbit, 309
Ryegrass : Preliminary Results of a Comparison between Tetraploid and Diploid (F. E. Alder), 546
Ryhage, R., *et al.* : Absence of Bile Salts in the Gastric Juice of a Crab, 301
Ryle, G. B. : Need for Forests in an Industrial Society, 953
Ryle, Prof. Martin awarded the Van der Pol Gold Medal, 241

SV-40 Complement-fixing Antigen : Production of (Dr. K. R. Schell), 417
Sabo, A. J., *et al.* : Inconstancy of Renal Clearance Values with Changing Plasma Concentrations, 143
Saccharomyces : Origin from Mitochondria of the Double-walled Viral Membrane in (Prof. C. C. Lindegren and Y. N. Bang), 431
  Palatinose Element of the Receptor of the Melezitose Locus in (D. S. Hwang and Prof. C. C. Lindegren), 791
Saccharomyces cerevisiae : Effect of Nicotinic Acid on Sterol Biosynthesis in (D. M. Bowen and Prof. R. E. Olson), 762
Sagittarius : OH Absorption Spectra in (S. J. Goldstein, jun., *et al.*), 65
Sahyun, M. R. V. : Enthalpy of Binding of Aromatic Amines to Bovine Serum Albumin, 1045
Sakai, R. K., and Johnson, F. M. : Leucine Aminopeptidase Polymorphism in *Drosophila buskii*, 373
Salam, M. A., and Wells, Dr. C. F. : Kinetic Approach to the Nature of Ferrous Ions in Aqueous Solution, 751
Salaman, Dr. M. H. : The Cytology and Cytochemistry of Acute Leukæmias, *review*, 683
Salinity in Sea Water : High (A. R. Miller), 590 ; (H. Charnock), 590
Salivary Glands : Histochemical Localization of Alkaline Phosphatase and Adenosine Triphosphatase in the Myoepithelial Cells of Rat (M. Shear), 770

Salles-Mourlan, A. M., et *al.* : Does a Connexion exist between Blood Group Modifications observed in Leukæmia and Certain Chromosomal Alterations ? 432
Salmon, Dr. G. A., et *al.* : Formation of Triplet States of Solutes in the Radiolysis of Organic Liquids, 1050
Salmon, Dr. J. E. : Salt Water Purification, *review*, 908
Salmonella typhimurium : Synthesis of Cystathionine and its Control in (Dr. R. J. Rowbury), 977
Salser, J. S., et *al.* : A Suggested Role of Amino-acids in Deoxyribonucleic Acid, 1170
Salt : Effect of Manganese on Water Content of 'Solar' (Dr. C. Sarasiti and Prof. E. B. Sandell), 60
Salt, G. F. H., et *al.* : *Leptospira erinacei auriti* in a Water Vole, *Arvicola amphibius*, 893
Salt Water Purification (Prof. K. S. Spiegler), *review* by Dr. J. E. Salmon, 908
Sammy, G., et *al.* : Methanolysis of 2,4-Dinitrophenyl *p*-Toluene Sulphonate, 637
Sandburg, A., et *al.* : Reduction in Rate of Growth of Hair in Mice as an Indicator of Exposure to Chronic Low Dosage Ionizing Radiation, 847
Sandell, Prof. E. B., and Surasiti, Dr. C. : Effect of Manganese of Water Content of 'Solar' Salt, 60
Sanders, Dr. J. H. : Soviet Maser Research, *review*, 335
Sanielevici, A., et *al.* : Calorimetric Dose Measurements with 35-MeV Betatron Electron Radiation, 632
Saponins : Growth-regulating Activity of some (Dr. J. C. Vendrig), 1301
Sarà, Prof. M., and Liaci, L. : Symbiotic Association between Zooxanthellae and Two Marine Sponges of the Genus *Cliona*, 321
Sarawak Museum Journal, 11, Nos. 21–22, 1123
Sarcoidosis : ABO Blood Groups in (Dr. G. Jörgensen and K. Wurm), 1095
Sarcoma-180 : Growth-retarding Effect of Oral L-Penicillamine on (Dr. M. L. Littman et *al.*), 726
Sárdy, F., et *al.* : Brown Adipose Tissue and Thermoregulatory Heat Production in the Rat, 765
Sarjant, Prof. R. J. : Advancement in Coke Technology, 585

Sobolev, V. V. : Treatise on Radiative Transfer, *review* by Dr. I. W. Busbridge, 112
Social Structure : Crime and the (Dr. John Barron Mays), *review* by Prof. D. C. Marsh, 109
Society for Applied Bacteriology : Officers elected, 1228
Society for Developmental Biology : Inaugural meeting, 126
Society for Folk Life Studies, fourth annual meeting, 700
Society for Water Treatment and Examination : Autumn meeting, 1018
Society of Cosmetic Chemists of Great Britain : Mr. A. Herzka elected president, 24
Sodium Bicarbonate : Measurement of Nitrogen Supplying-power of Soils by Extraction with (A. A. MacLean), 1307
Sodium Deoxycholate on the Intestinal Mucosa of the Mouse : Effect of a Diet containing (Dr. R. J. M. Fry and Dr. E. Staffeldt), 1396
Soil : Electro-osmosis in Frozen (Dr. P. Hoekstra and E. Chamberlain), 1406
  Semi-quantitative Method of Counting Nematode-trapping Fungi in (H. W. Klemmer and R. Y. Nakano), 1085
Soil-Plant-Animal Complex (Dr. T. G. Taylor), 924
Soil Science : Agricultural (R. I. Davies), 133
  Treatise on (K. D. Glinka), fourth posthumous edition, revised, *review* by Dr. C. Bloomfield, 334
Soil/Solution Ratio on Determining the Chemical Potentials of Phosphate Ions in Soil Solutions : Effect of (S. Larsen and A. E. Widdowson), 942
Soil and Uptake by Plants : Soluble Phosphate in (Dr. A. Wild), 326
Soils : Chemical Analysis of (K. K. Gedroits), *review* by Dr. C. Bloomfield, 334
Soils by Extraction with Sodium Bicarbonate : Measurement of Nitrogen Supplying-power of (A. A. MacLean), 1307
Solar Activity : Collision Frequency in the Ionosphere and (Prof. W. J. G. Beynon and E. S. O. Jones), 1159
Solar Chromosphere : Structure of the (Prof. P. A. Sturrock), 285
Solar Cycle : Slowly Varying Component of Solar Radio Emission in Relation to the (Dr. M. K. Das Gupta and D. Basu), 626
Solar Radio Emission in Relation to the Solar Cycle : Slowly Varying Component of (Dr. M. K. Das Gupta and D. Basu), 626
'Solar' Salt : Effect of Manganese on Water Content of (Dr. C. Surasiti and Prof. E. B. Sandell), 60
Solar X-ray Emission in the Band 44–60 Å from U.S. Naval Research Laboratory Satellite : Observations of (Dr. L. Thomas), 962
Soliman, Dr. H. A., et *al.* : Extraction and Purification of Calcitonin, 1027
Solomon Islands, Royal Society Expedition, 696

Solubilities of Inorganic and Organic Compounds (edited by Prof. H. Stephen and Dr. T. Stephen), Vol. 1, Part 2, *review* by P. J. Cooper, 339
Soluble Lens Proteins in Lactose-fed Rats : Paper Electrophoresis of (Dr. I. Korc, *et al.*), 649
Soluble Liver Proteins Fractionation by Zone Electrophoresis on 'Pevikon C-870' (Dr. V. Bocci), 775
Soluble Phosphate in Soil and Uptake by Plants (Dr. A. Wild), 326
"Solution Properties of Polymers", short course, 1337
Solvent, Effect of the Spreading, on Monolayer Properties (D. C. Walker and Dr. H. E. Ries, jun.), 292
Solway Firth Barrage, 816
Some Aspects of East African Vulcanology (W. H. Wilcockson), 949
"Some Physical Aspects of Oceanology in Shallow Seas", international summer course, 128

Teratogenic Risks of Drug Synergism (W. Landauer and E. M. Clark), 527
"Teratology", course of lectures, 462
Terbium Ion Chelate in a Vinylic Resin Matrix : Additional Observations of Probable Stimulated Emission of a (E. H. Huffman), 1373

Termite Studies in Africa, 349
Terrestrial Globes in Investigations of Palæomagnetism and Continental Drift : Preparation of Spherical Caps for Use on (Prof. J. Hospers), 397
Tertiary Structure : Relation of Protein Evolution to (Dr. C. J. Epstein), 1350
Testes-DNA, Effect of Chemical Protective Agents (Cysteamine and β-Aminoethylisothiuronium (AET) Cl HCl) and Homologous, on the Death-rate of the Progeny of a First Generation originating from Male Rats irradiated in the Infantile Period (Dr. N. Savković), 1393
Testes-DNA of Rats irradiated during the Infantile Period : Recovery of Reproductive Ability by Homologous (Dr. N. Savković), 1297
Testis : Isolation of a Soluble RNA Polymerase from Rat (P. Ballard and Prof. H. G. Williams-Ashman), 150
Testis of the Sheep and Rat : Variations in Flow of Blood within the Epididymis and (Dr. B. P. Setchell *et al.*), 317
Testosterone : Carrier-free (7-^{3}H)- (Dr. M. M. Coombs and H. R. Roderick), 523
Tetracycline : Development *in vitro* of Bacterial Cross-resistance involving Penicillins, Chloramphenicol and (R. Sutherland *et al.*), 548
Tetracycline-treated Rats : Bone Growth and Uptake of Radiocalcium in (Dr. R. C. Likins and G. A. Pakis), 1069
Tetrad Analysis by Autoradiography (K. M. Marimuthu and Prof. S. F. H. Threlkeld), 101
Tetrafluoroethylene with Pentacyanocobaltate Ions and with Reduced Vitamin B_{12} : Reaction of (M. J. Mays and Prof. G. Wilkinson), 1167
Tetragalacturonic Acids by a Transeliminase : Effect of the Unsaturated Bond on the Degradation of the (M. M. Anderson and Prof. C. W. Nagel), 649
Tetrahedral Anvil Apparatus below 25 Kilobars : Load Discontinuity Method for Pressure Calibration : (J. Lees), 965
Tetrahydropapaveroline from Dopamine *in vitro* : Formation of (Prof. P. Holtz, K. Stock and E. Westermann), 656
Tetrahymena : Distribution and Fate of 2-Aminoethylphosphonic Acid in (Dr. H. Rosenberg), 299
Tetramer : Structure of the β-Lactoglobulin (S. N. Timasheff and R. Townend), 517
Tetraploid and Diploid Ryegrass : Preliminary Results of a Comparison between (F. E. Alder), 546
Tew, jun., Dr. J. M., and Li, Dr. C.-L. : Reciprocal Activation and Inhibition of Cortical Neurones and Voluntary Movements in Man : Cortical Cell Activity and Muscle Movement, 264
Textiles, Colour Chemistry and Dyeing : Research in, 244
Thackray, M. : Vapour Pressure Equations and Melting Points of Allotropes of Sulphur and the α-γ Transition Point, 1278
Thaine, Dr. T. : Cytoplasm Exudate from Cut Phloem, 544
Theileria in Cultures of Bovine Lymphocytic Cells : Mode of Multiplication of (Dr. L. Hulliger *et al.*), 728
Theobald, Dr. G. W., *et al.* : Potentials evoked in the Hypothalamus and Cerebral Cortex by Electrical Stimulation of the Uterus, 654
Theorell, Prof. H., *et al.* : Optical Rotatory Dispersion of Liver Alcohol Dehydrogenase and its Complexes, 755
Theoretical Model of γ-Globulin Catabolism (Prof. F. W. R. Brambell, Dr. W. A. Hemmings and Dr. I. G. Morris), 1352
Theory of Plasma Waves (Prof. T. H. Stix), *review* by Prof. V. C. A. Ferraro, 224
Theory of Striations in Gas Discharges (Prof. L. Gold), 855
Theory of the *p*H-stat Titration of a Polyfunctional Reactant by a Competitive 'Ligandee' (Dr. S. Katz), 858
Thermal Annealing of Tellurium resulting from Isomeric Transition in Solid Sodium Tellurate (D. Dancewicz and Dr. A. Halpern), 856
Thermal Changes in the *Nautilus* Shell (Dr. Ch. Grégoire), 868
Thermal Conductivity of Gas Mixtures : A Flow Method for Determining the (E. V. Evans and Dr. C. N. Kenney), 184
Thermal Decomposition of Barium Azide (Prof. E. G. Prout and D. J. Moore), 860
Thermal Expansion of Pyrolytic Graphite and its Variation due to Non-alignment of the Crystallites (R. H. Knibbs and I. B. Mason), 58
Thermal Initiation Theory in Interpreting the Results of Fission Fragment Irradiation of Explosives at Elevated Temperatures : Inadequacy of (Lt. J. F. Mallay *et al.*), 473 ; (T. Boddington, *et al.*), 473
Thermal Proteinoids : Catalytic Decomposition of Glucose in Aqueous Solution by (Prof. S. W. Fox and Dr. G. Krampitz), 1362
Thermal and Translocated Induction of Endophytic Mycelium in two Powdery Mildews (W. R. Jarvis), 895
Thermionic Emission and Heat of Hydration of Lime (A. K. Chatterji, T. C. Phatak and K. D. Dhariyal), 61
Thermoelectric Device for Inducing Local Tissue Hypothermia and Hyperthermia (Dr. D. M. Makow and Dr. H. C. Grice), 613
Thermophilic Fungi associated with Nigerian Oil Palm Produce (Dr. H. O. W. Eggins and D. G. Coursey), 1083
Thermophylaxis in Bean Rust (Prof. C. E. Yarwood), 426
Thermoregulatory Heat Production in the Rat : Brown Adipose Tissue and (Prof. Sz. Donhoffer *et al.*), 765
Theta Rhythm prior to Awareness of a Visual Stimulus : Incidence of (Dr. N. F. Dixon and Dr. T. E. Lear), 167
Thiamin and 2,4-Dichlorophenoxyacetic Acid : Formative Response of *Amsinckia intermedia* to the Interrelated Effects of Low Temperature (W. G. Mauldin and Prof. T. J. Muzik), 427
Thin-layer Chromatography: Analysis of Algal Pigments by (Dr. J. S. Bunt), 1261
Thin-layer Chromatography Group : meeting, 819
Thiocyanate on Secretion of Acid and Uptake of Oxygen by Gastric Mucosa of the Frog : Effect of (W. H. Bannister), 978
Thiol Groups of Adenosine Triphosphate-creatine Phosphotransferase : Amino-acid Sequence around the Reactive (Dr. A. R. Thomson *et al.*), 267
Thiol Groups of Proteins : New Chromophoric Reagents for Labelling the (S. F. Chang and Prof. I. E. Liener), 1065
Thoday, Prof. J. M., and Gibson, J. B. : Balanced Combinations of Polygenes, 102
Thomas, A. S. : Journey to the Jade Sea, *review*, 1211

Time-dependent Inhibition of Myogenesis by Actinomycin *D* (Dr. P. Pietsch), 1177
Timpl, R., *et al.* : Panagglutination of Erythrocytes coupled with Diazotized *p*-Nitroaniline, 1076
Tintagel, Cornwall : Early Folds and the α-Lineation at (Dr. W. R. Dearman *et al.*), 933
Tippett, J. T., *et al.* (edited by) : Optical Processing of Information, *review* by Prof. D. Gabor, 905
Tissue Culture : Extracts of Mould-infected Groundnut Samples in (S. Juhász and E. Gréczi), 861
  Metabolic Activity of Neural Crest Tumours in (Dr. E. H. La Brosse *et al*), 195
  Phytohæmagglutinin-induced Cytotoxic Action of Normal Lymphoid Cells on Cells in (Dr. G. Holm *et al.*), 841
Tissue Cultures by Gibberellic Acid : Promotion of Cell Division in (J. Digby *et al.*), 547
Tissue soluble Proteins with Iodine-131 using Chloramine *T* : Efficient Labelling of (Dr. V. Bocci), 985
Tissues : Presence of Imidazoleacetic Acid Riboside and Ribotide in Rat (Dr. J. D. Robinson and Dr. J. P. Green), 1178
Titanium Dioxide–Silver Nitrate Mixtures after Ultra-violet Irradiation : Changes in (Dr. W. C. Clark and A. Vondjidis), 635
Titanium Trichloride in Natta's Polymerization : Role of Grinding of (Prof. T. Keii and T. Akiyama), 76
Tlamicha, A., and Wild, J. P. : Spectral Evidence on the Origin of Type I Solar Radio Storms and the Coronal Magnetic Field, 1128
Tobacco Mosaic Virus : Effect of 5-Fluorouracil on Antigenic Properties of (Prof. D. Sutić and B. Djordjević), 434
Tobacco Mosaic Virus Protein on Tobacco Mosaic Virus Infectivity : Effect of (Dr. V. Holoubek), 499
Tobias, Prof. J. M. : A Chemically Specified Molecular Mechanism Underlying Excitation in Nerve : A Hypothesis, 13
Todd, Dr. G., and Parry, E. Role of Silica in the Oxidation Resistance of Molybdenum Disilicide, 967
Todd, Prof. John : Introduction to the Constructive Theory of Functions, *review* by Prof. T. A. A. Broadbent, 114
Tomato Fruits : Cellulase in (D. B. Dickinson and J. P. McCollum), 525
Tomato Plants of *Azotobacter* Inoculation and Application of Gibberellins : Similar Effects on (Dr. R. M. Jackson, M. E. Brown and S. K. Burlingham), 851
Tomato Spotted Wilt Virus : Lipid in a Purified Preparation of (Dr. R. J. Best and G. F. Katekar), 671
Tomato Stems and Leaves : Feeding of Vitamin C to (Prof. P. Hagene and J. Trichet), 783
Tomblin, J. F., *et al.* : Survey of the South Sandwich Islands, 691
Tomlin, J. F., and Baker, P. E. : A Recent Volcanic Eruption on Bouvetoya, South Atlantic Ocean, 1055
Tonge, Dr. R. J., *et al.* : Effects of Inositol-deficiency on Yeast with Particular Reference to Chemical Composition of the Cell and of the Cell Wall, 250
Tongue : Apparent Size of Holes felt with the (Dr. S. M. Anstis), 792
Tonks, Dr. L., and Baldwin, Dr. G. C. : Logarithmic Pressure Scale, 633
Tonolo, A., *et al.* : Fusicoccin : a New Wilting Toxin produced by *Fusicoccum amygdali* Del, 297
Tooze, J., and Davies, Dr. H. G. : Electron Microscope Observations on Mitotic Chromosomes in Erythroblasts of the Newt, *Triturus cristatus cristatus*, 990
Toro-Goyco, Dr. E., and Matos, M. : Purification of Pinguinain by Gel-Filtration, 82
Torry Research Station, 918
Torrens, I. McC., and Chadderton, Dr. L. T. : Electron Microscope Observation of Nuclear Reactions, 387

Tottle, Prof. C. R. : Nickel : an Historical Review, *review*, 336
Towards a Policy for Technical Co-operation, 439
Towards Better Utilization of Scientific and Engineering Talent : *A Program for Action*. Report of the Committee on Utilization of Scientific and Engineering Manpower Publication No. 1191. National Academy of Sciences, 1101, 1125
Townend, R., and Timasheff, S. N.: Structure of the β-Lactoglobulin Tetramer, 517
Townsend, C. C. : Structure and Life of Bryophytes, *review*, 1002
Toxic Action of Hæmolytic *Escherichia coli* isolated from Pigs (S. L. Chopra and Prof. A. C. Blackwood), 667
Toxin, a New Wilting, produced by *Fusicoccum amygdali* Del : Fusicoccin : (A. Ballio et *al*.), 297
Toxoids : Specific Precocious Protective Action of (Dr. J. Mellanby and Dr. W. E. van Heyningen), 312
Trace Elements : Analysis of Petroleum for (O. I. Milner), *review* by E. Thornton, 685
Traffic Problems and Industrial Development in Britain, 219
Traité de Psychologie Expérimentale (Sous la direction de Paul Fraisse et Jean Piaget), Vols. 1, 2, 5 and 6, *review* by Prof. O. L. Zangwill, 109
Trakatellis, Dr. A. C., et *al*. : Actinomycin *D* and Messenger-RNA Turnover, 1134
Transactions of the American Philosophical Society (New Series—Vol. 54, Part 1 : Rome and the City of God (Prof. K. F. Morrison), *review* by M. C. Burkitt, 681
Transactions of the Palaeontological Institute, U.S.S.R., 1227
Transeliminase : Effect of the Unsaturated Bond on the Degradation of the Tetragalacturonic Acids by a (M. M. Anderson and Prof. C. W. Nagel), 649
Transfer of Melanin Granules from Melanocytes to the Cortical Cells of Human Hair (Dr. J. A. Swift), 976
Transfer of Oxytocin from the Maternal to the Fœtal Circulation in the Ewe (Miss B. A. Noddle), 414
Transferrin D_1 in Korea : Occurrence of (B. S. Shim), 432
Transferrin Variation in Kangaroos (D. Cooper and G. B. Sharman), 1094
Transformation of Embryonic Human Cells by Rous Sarcoma Virus (Dr. L. Zilber and V. Shevijaghyn), 194
Transition Metal Ions with Triply Orbitally Degenerate Ground Terms : Trigonal or Tetragonal Distortions and the Magnetic Properties of (Dr. B. N. Figgis et *al*.), 1138
Translocated Induction of Endophytic Mycelium in two Powdery Mildews : Thermal and (W. R. Jarvis), 895
Transmission of Colicinogeny to *Providence* Strains (Prof. J. N. Coetzee), 897
Transplantation : Effect of Œstradiol on Bone Marrow, in Lethally Irradiated Mice (Dr. J. S Thompson et *al*.), 265
Transuranium Elements : Man-made (Prof. G. T. Seaborg), *review* by Dr. A. G. Maddock, 906
Transuterine Ligation of the Umbilical Cord : Fœtal Exclusion by (Dr. D. Lehr et *al*.), 736
Transvaal Museum, annual report, 1336
Trapped Charges on Dielectrics (D. K. Davies), 290
Treasury Control of Establishments : Fifth Report from the Estimates Committee together with the minutes of the Evidence taken before Sub-Committee C and Appendixes, Session 1963–64, 797
Treasury, The (The Rt. Hon. Lord Bridges), 555
Treatise on Analytical Chemistry, Part I, Vol. 4 (edited by I. M. Kolthoff and Philip J. Elving), *review* by J. Thomson, 447
Treatise on Radiative Transfer (V. V. Sobolev), *review* by Dr. I. W. Busbridge, 112
Treatise on Soil Science (K. D. Glinka), fourth posthumous edition, revised, *review* by Dr. C. Bloomfield, 334
Trees : Formation of Wood in Forest (edited by Martin H. Zimmermann), *review* by Dr. C. J. Taylor, 909
Trematodes of Animals and Man : Keys to the (K. I. Skrjabin et *al*.), *review* by Prof. Ben Dawes, 1318
Trench, C. A. H., et *al*. : Inhibition of Tumour Growth in Irradiated Mice by Sensitized Homologous Spleen Cells, 1295
Trevena, Dr. D. H. : Propagation of Stress Pulses across a Liquid-steel Boundary, 291
    Stress Waves in a Liquid Column, 1158
Trevena, Dr. D. H., and Rees, E. P. : Effect of Precompression on the Critical Tension of Liquids, 396
Trichet, J., and Hagene, Prof. P. : Feeding of Vitamin C to Tomato Stems and Leaves, 783
Trichostrongylus colubriformis (a Nematode Parasite of Sheep and Other Ruminants) as a Test Organism in Screening for Sheep Anthelmintics in the Laboratory (G. A. H. Williams and B. H. Palmer), 1399
5′,5′,5′-Trifluoroleucine on a Number of Mouse Leukæmias : Effect of (O. M. Rennert and H. S. Anker), 1256
Trigonal or Tetragonal Distortions and the Magnetic Properties of Transition Metal Ions with Triply Orbitally Degenerate Ground Terms (Dr. B. N. Figgis, Prof. J. Lewis, Dr. F. Mabbs and Dr. G. A. Webb), 1138
Triplet States of Solutes in the Radiolysis of Organic Liquids : Formation of (Prof. F. S. Dainton, Dr. T. J. Kemp, Dr. G. A. Salmon and Dr. J. P. Keene), 1050
Trites, D. H., et *al*. : Structural Investigation of 4-[(-Amino-5-pyrimidinyl)-imino]-2-penten-2-ol, 970
Triticum aestivum : Cytological Determination of the Homœology of Chromosomes of (Dr. R. Riley and V. Chapman), 156
'Triton' Hyperlipæmic Guinea Pigs : Failure to induce Atherosclerosis in (Dr. G. B. Rossi et *al*.), 416
Triturus cristatus cristatus : Electron Microscope Observations on Mitotic Chromosomes in Erythroblasts of the Newt (Dr. H. G. Davies and J. Tooze), 990
Trolle, Dr. B. : *obituary* of Prof. Ø. Winge, 123
Tropical Meteorology in Africa (edited by D. J. Bargman), *review* by Dr. R. C. Rainey, 561
Tropical Populations : Malaria Antibody Content of Gamma$_2$-7*S* Globulin in (Dr. C. C. Curtain et *al*.), 1366
Trotter, W. R., and Pitt-Rivers, R. : Thè Thyroid Gland, Vols. 1 and 2, *review*, 1210
Trypsin by Paper Electrophoresis : Fractionation of (A lachan et *al*.), 43
Trypsin, Urinary, Inhibitor (Mingin) : Transformation into a New Trypsin Inhibitor by Acid Hydrolysis or by Sialidase (Dr. T. Astrup and U. Nissen), 255
Tryptamine Excretion in Schizophrenic Patients : Variations of Urinary Creatinine and its Correlation to (Dr. H. H. Berlet et *al*.), 1198
Tryptophan Deficiency in the Very Young Chicken : Growth Stasis and (R. S. Gordon), 320
Tsetse Flies in Northern Nigeria (H. Davies), *review* by R. W. Crosskey, 686
Tuberculin Skin Reaction : Early Regressive Changes during the (Dr. A. Kolín), 882
Tulecke, Dr. W. : A Haploid Tissue Culture from the Female Gametophyte of *Ginkgo biloba* L., 94
Tulkens, P., et *al*. : Influence of the Injection of a Sucrose Solution on the Properties of Rat-liver Lysosomes, 757
Tumour Growth in Irradiated Mice by Sensitized Homologous Spleen Cells : Inhibition of (Dr. P. S. Gardner, C. A. H. Trench, Prof. C. A. Green and T. Bird), 1295
Tumours by means of Herpes Simplex and Polyoma Viruses : Artificial Heterogenization of (V. P. Hamburg and Dr. G. J. Svet-Moldavsky), 772
Tumours in Mice : Effect of Early Thymectomy on Development of Mammary (Prof. C. Martinez), 1188
Tumours induced in Rats by Oral Administration of Dimethylbenzanthracene : Relationship of Adrenocortical Insufficiency to Spontaneous Regression in Mammary (Dr. S. Young et *al*.), 1079
Tumours of the Mouse : *ML* : A New Antigen found in Leukæmias and Mammary (Dr. B. Stück et *al*.), 1033
Tumours Transplanted in Cheek Pouch of Syrian Hamster : Effect of Colchicine on Human (Dr. Giuseppe Cardinali et *al*.), 90
Tunas, Body Temperature of Yellowfin and Skipjack in Relation to Sea Surface Temperature (I. Barrett and F. J. Hester), 96
Tungsten : Oxygen Diffusion in (Dr. C. H. Lee), 1163
Tunnelling-induced Injection in *p-n* Junctions (Prof. M. A. Melehy), 1276
Turbyfill, C., et *al*. : High Resistance of Mongolian Gerbils to Irradiation, 536
Turkeys : Hæmagglutination Reaction with Vaccinia Virus : Agglutinability of Red Cells from (Dr. N. S. Datt), 1406
Turnbull, Dr. D., and Cohen, Prof. M. H. : Metastability of Amorphous Structures, 964
Turner, Miss Leslie, et *al*. : Mode of Multiplication of *Theileria* in Cultures of Bovine Lymphocytic Cells, 728
Turner, M. K., and Reid, E. : Anomalous Effect of Ethionine on Ribonucleic Acid Synthesis, 1174
Turner, P., and Smart, J. V. : Modification of Visual Critical Flicker Fusion Frequency by Intermittent Auditory Stimuli, 1387
Turrill, Dr. W. B. : Joseph Dalton Hooker, *review* by B. L. Burtt, 221
Twigs of Angiospermous Plants : Specific Inhibition of Anti-Rh Antibodies by Extracts from (Prof. G. F. Springer and Mrs. H. Tegtmeyer), 298
Two-nucleon Interaction (M. J. Moravcsik), *review* by J. M. Soper, 910
Tyler, J. F. C. : Modern Polarographic Methods, *review*, 1212

UGOLEV, A. M., et *al*. : Localization of Invertase Activity in Small Intestinal Cells, 879
Ultra-centrifugal Forces : Survival of Ehrlich's Ascites Carcinoma Cells at High (Dr. N. Molomut et *al*.), 740
Ultra-violet Absorption Spectrum of the Free Fulminate (C—N—O) Radical (Dr. W. D. McGrath and T. Morrow), 619
Ultra-violet Damaged Deoxyribonucleic Acid in Cultured Mammalian Cells : Evidence for Repair of (Dr. R. E. Rasmussen and Dr. R. B. Painter), 1360
Ultra-violet Irradiation : Changes in Titanium Dioxide–Silver Nitrate Mixtures after (Dr. W. C. Clark and A. Vondjidis), 635
Ultra-violet Radiation : Photolysis of Nitrosyl Chloride by (Dr. P. P. Wayne), 516
Ultra-violet and X-irradiated Bovine Serum Albumin : Electron Spin Resonance Investigations of (Prof. R. Koch and H. Mönig), 859
Umbilical Cord : Fœtal Exclusion by Transuterine Ligation of the (Dr. D. Lehr et *al*.), 736
Unanæsthetized Animal : Simultaneous Recording of Electrical and Mechanical Activity of the Uterus in the (Dr. P. Bass and M. R. Callantine), 1367
Underwater Acoustics: Proceedings of an Institute sponsored by the Scientific Affairs Committee of the North Atlantic Treaty Organization, London, 1961 (edited by V. M. Albers), *review* by Dr. J. S. M. Rusby), 1320
Ungar, F., et *al*. : Non-enzymatic Interactions of Reduced Coenzyme I with Inorganic Phosphate and Certain Other Anions, 973
Unit Cell and Space Group of $\text{Co(thiourea)}_4(\text{NO}_3)_2$ (M. P. Rodriguez, Dr. M. Cubero and M. Garcia Gea), 513
United Kingdom Atomic Energy Authority, tenth annual report, 1338
United Kingdom Atomic Energy Authority. Atom 1954/1964 : *an Illustrated Summary of the Tenth Annual Report*, 1339
United Nations Special Fund, 817
United States : Scientific and Engineering Man-power in the, 1101, 1125
United States Library of Congress : Dr. E. Wenk, jun., appointed to the Science Policy Research Division, 1120
United States Man-power Requirements in Science, Engineering and Technology, 22
United States National Science Foundation Division of Engineering, 348
Units Sensitive to Direction of Movement in Goldfish Optic Tectum (Dr. J. R. Cronly-Dillon), 214
Units, Suggested, for Conductivity (R. E. Barker, jun.), 513
Universities : Film and Television in the Work of the (C. E. Engel), 1125
Universities Federation for Animal Welfare, summer congress, 128
Universities of Newcastle and Durham, eighteenth annual report of the Appointments Board, 348
University in the Making (Dr. A. E. Sloman). (The Reith Lectures 1963), 107
University Library Services, 243
University of Aberdeen : Appointments, 351
    Chair of Anatomy, 1225
University of Belfast : Appointments, 461
University of Birmingham : Appointments, 461, 700, 1227
    Bowman chair of physiology, 696
    Second chair of geography, 458
University of Bristol : Appointments, 24, 462
University of Cambridge : Clare Hall, 240
    Master of Darwin College appointed, 920
    Report of the Engineering Department 1962–63, 351
University of Durham : Chair of applied mathematics, 1225
University of East Anglia : Appointments, 24, 578
    Chair of chemistry, 21
University of Edinburgh : Appointments, 462
University of Exeter : Chair of Physical Chemistry, 125
University of Glasgow : Report of the Appointments Committee, 1963, 1016
    Report on Recruitment to School Teaching, 1121
University of Hull : Chair of theoretical physics, 457
University of Leeds : Appointments, 24, 819
    Chair of Fibre Science, 815
University of Liverpool : Appointments, 351
    Chair of experimental physics, 457
    Chair of physical metallurgy, 457
    Joint research reactor with University of Manchester, 348
University of London : Appointments, 128, 578, 700, 819, 919, 1018, 1228, 1334
    Chair of botany, 1225

University of Manchester : Chair of Medical Biochemistry, 816
Chair of physics, 696
Joint research reactor with University of Liverpool, 348
University of Newcastle upon Tyne : Appointments, 462
Chair of geography, 128
University of Oxford : Annual report of the Curators of the Bodleian Library, 920
Chair of Physical Chemistry, 917
University of Reading : Chair of mathematics, 347
The Cole Library, 239
University of St. Andrews : Appointments, 351
University of Sheffield : Appointments, 462, 819
Chair of physical geography, 1015
University of Southampton : Appointments, 128, 578
Awarded grant from Department of Scientific and Industrial Research, 128
Chair of Electrical Power Engineering, 815
Prof. K. Mather appointed Vice-Chancellor, 24
University of Stirling, 458
University of Strathclyde : Appointments, 1121
Department of Pure and Applied Chemistry, 125
University of Sussex : Appointments, 351
Chair of experimental psychology, 816
Chair of social psychology, 1014
Grant received for the establishment of a race relations unit, 462
School of applied sciences, 815
Unthank, E. L., *et al.* : Simultaneous Sampling at Different Altitudes, 289
Unusual Forms and Aspects of Cancer in Man (Dr. F. J. C. Roe), 356
Upper-atmosphere Density, Variations in, between Sunspot Maximum and Minimum (D. G. King-Hele), 959
Upper Mantle at Eskdalemuir, South Scotland : Electrical Resistivity of the Crust and (S. Jain), 631
Uptake of γ-Globulin and Complement by Red Cells exposed to Serum at Low Ionic Strength (Prof. P. L. Mollison and M. J. Polley), 535
Uptake of Hydrocarbon Carcinogens by Lysosomes (Dr. A. C. Allison and Dr. L. Mallucci), 1024
Uptake and Binding of Chloramphenicol by Sensitive and Resistant Organisms (Dr. D. Vazquez), 257
Uranium from Sea Water : Extraction of (R. V. Davies et *al.*), 1110
Uranium and Lead estimated from the Isotopic Composition of Lead in Ores : Relative Distribution of Thorium (A. Masuda), 1062
Urch, Dr. D. S. : Electronic Structures of Kryptates and Xenates, 403
Urea on A_2 Influenza Virus : Effect of (D. C. Dorman), 780
Urethane : Potentiation of Virus Leukæmogenesis in *C57BL* Mice by X-irradiation or (Dr. M. Lieberman et *al.*), 420
Urinary Calculi in Rats exposed to High Concentrations of Oxygen with Added Carbon Dioxide : Occurrence of (Prof. C. W. Smith and F. A. DeClement), 85
Urinary Creatinine and its Correlation to Tryptamine Excretion in Schizophrenic Patients : Variations of (Dr. H. H. Berlet et *al.*), 1198
Urinary Mucoprotein : Specific Inhibition of Anti-*D* by Human (Dr. H. W. Johnson and M. C. Dodd), 1082
Urinary Trypsin Inhibitor (Mingin) : Transformation into a New Trypsin Inhibitor by Acid Hydrolysis or by Sialidase (Dr. T. Astrup and U. Nissen), 255
Urine : Conjugated Oxosteroids in Human (Dr. H. L. Kay and Prof. F. L. Warren), 406
Urine of Children but not Adults : A New Steroid found in the (D. Gupta and Dr. J. M. Tanner), 187
Urine and Plasma and their Relation to 7*S* γ_2-Globulin : Low Molecular Weight γ-Globulins of (P. Fireman et *al.*), 78
Urist, Dr. M. R., and Ibsen, Dr. K. H. : Relationship between Pyrophosphate Content and Oxytetracycline Labelling of Bone Salt, 761
Uronic Acid Residues : A Proposed Pathway for the Biosynthesis of Pectin and Methylated (Dr. F. A. Loewus), 1175
Urrusti J. et *al.* : Selective and Directional Transfer of 7*S* γ_2-Globulin across the Human Placenta, 86
Urso, P., and Gengozian, Dr. N. : Immunofluorescent Detection of Proliferating Human Antibody-forming Cells, 1391
"Use of Film in Higher Education and Research", conference on, 240
"Use of Radioisotopes in Animal Nutrition and Physiology", symposium, 1337
Uses of the University (C. Kerr), 108
Uterine Uptake of Catecholamines : Effects of Lumbar Sympathectomy on the (Dr. J. E. Fischer et *al.*), 938
Uterus : Potentials evoked in the Hypothalamus and Cerebral Cortex by Electrical Stimulation of the (Dr. V. C. Abrahams et *al.*), 654
Uterus in the Unanæsthetized Animal : Simultaneous Recording of Electrical and Mechanical Activity of the (Dr. P. Bass and M. R. Callantine), 1367
Utilization of Scientific and Engineering Man-Power, 1101, 1125

VACCINE : Preparation of Soluble *Pertussis* (P. Van Hemert et *al.*), 774
Vaccinia Virus : Hæmagglutination Reaction with : Agglutinability of Red Cells from Turkeys (Dr. N. S. Datt), 1406
Vachrameev, V. A., et *al.* (edited by) : Fundamentals of Palæontology, Vol. 15, *review* by Dr. W. G. Chaloner, 685
Vacuum Technology (Prof. A. Guthrie), *review* by J. Yarwood, 682
Vaerman, Dr. J. P., et *al.* : Direct Demonstration of Reagin Activity in Purified γ_{1A}-Globulin, 1046
Valenta, Dr. P., and Koryta, Dr. J. : Determination of Electro-oxidation Products using an Auxiliary Mercury Electrode, 639
Valentine, Prof. F. A. : (edited by) : Manual of Experiments in Reactor Physics, *review* by J. F. Hill, 804
Valentine, Dr. R. C., and Wrigley, N. G. : Graininess in the Photographic Recording of Electron Microscope Images, 713
Van Allen, J. A. : Lifetimes of Geomagnetically Trapped Electrons of Several MeV Energy, 1006
van Allen Belt : Evidence for Asymmetry of Jupiter's (J. A. Roberts and M. M. Komesaroff), 827
Van Citters, R. L., et *al.* : Blood Velocity telemetered from Untethered Animals, 528
van den Oord, A., et *al.* : Absence of Bile Salts in the Gastric Juice of a Crab, 301
van der Plank, J. E. : Plant Diseases, *review* by W. C. Moore, 1106
van der Pol, Balthazar, Gold Medal for Scientific Radio (Dr. R. L. Smith-Rose), 241
van Dorp, D. A., et *al.* : Enzymatic Conversion of All-*cis*-Polyunsaturated Fatty Acids into Prostaglandins, 839
van Hemert, P., et *al.* : Preparation of Soluble *Pertussis* Vaccine, 774
van Heyningen, Dr. W. E., and Mellanby, Dr. J. : Specific Precocious Protective Action of Toxoids, 312
Van Middlesworth, Prof. L. : Long-life Radioactivity in Occasional Thyroids, 199
van Niel, Prof. C. B. (edited by) : Selected Papers of Ernst Georg Pringsheim, *review* by Dr. S. T. Cowan, 909
van Wezel, A. L., et *al.* : Preparation of Soluble *Pertussis* Vaccine, 774
Van Wijk, W. R. (edited by) : Physics of Plant Environment, *review* by Dr. J. L. Monteith, 444
Vapour Pressure Equations and Melting Points of Allotropes of Sulphur and the α-γ Transition Point (M. Thackray), 1278
Vapours : Evidence for Sorption as a Mechanism of the Olfactory Analysis of (Prof. M. M. Mozell), 1181
Variation in the Electrophoretic Pattern of Human Erythrocyte Carbonic Anhydrase (Dr. R. F. Rieder and Dr. D. J. Weatherall), 1364
Varma, Dr. M. G. R., et *al.* : Isolation of Louping *ill* Virus from Small Mammals in Ayrshire, Scotland, 992
Varro and the Small Beasts : A Bimillennium for Microbiologists (Dr D. F. Cheesman), 911
Vascular Permeability in the Rat : Effect of RNA on (D. A. Willoughby, et *al*), 882
Vascular Smooth Muscle of the Rat : Electrical and Mechanical Activity of Isolated (Dr. S. Funaki and Prof. D. F. Bohr), 192
Vasomotor Effect of Isoprenaline : Mechanism of Reversal of the (Dr. J. Gutman and Dr. J. Beyth), 1291 ; (Dr. K. R. Butterworth), 1291
Vaughan, R. W., et *al.* : Survey of the South Sandwich Islands, 691
Vaz Dias, H., et *al.* : α-Glycerolphosphate Production by Rat Hepatomas, 77
Vazquez, Dr. D. : Uptake and Binding of Chloramphenicol by Sensitive and Resistant Organisms, 257
Vecchione, A., et *al.* : Deoxycorticosterone Acetate and Experimental Atherosclerosis in Cholesterol-fed Rabbits, 252
Failure to induce Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs, 416
Vegetative Anatomy of Plants (H. G. Burström and C. Odhnoff), *review* by Dr. C. R. Metcalfe), 1005
Venable, jun., Dr. J. H., and Brill, Prof. A. S. : Electron Paramagnetic Resonance in Single Crystals of Cupric Insulin, 752
Vendrig, Dr. J. C. : Growth-regulating Activity of some Saponins, 1301
Venous Blood of Normal Adults : Free α-Amino-N Content of Peripheric and Hepatic (Dr. D. Müting and L. Bette), 192
Venus : Stability of Hydrogen Compounds on (Dr. R. F. Mueller), 625
Vereshchagin, A. G., and Novitskaya, G. V. : Anomalous Ionization of Methyl Linolenate by Metastable Argon Atoms : Possible Linolenic Acid Participation in Photosynthetic Reactions, 1384
Verly, Dr. W. G., and Petitpas-Dewandre, A. : Utilization of Labelled 'Myleran' for the Determination of the Size of DNA Molecules in Cells, 865
Very-low frequency Emissions : Anomalous Doppler Radiation and (Prof G. R. A. Ellis), 1271
Vesonder, R. F., et *al.* : A $C_{16}H_{22}O_4$ Compound produced by the Fungus *Aspergillus fischeri* var. glaber, 1382
Vessey, K. B., et *al.* : Mechanisms of Inactivation of Single-stranded Virus Nucleic Acids by Heat, 606
Veterinary Annual 1963/64 (edited by W. A. Pool), fifth year, *review* by G Lapage, 1212
Viale, R. O., et *al.* : Molecular Orbital Evidence for Weiss's Oxyhæmoglobin Structure, 183
Vick, Capt. J. A., et *al.* : Effect of Snake Venom and Endotoxin on Cortical Electrical Activity, 1387
Vicker, D. H., and Mitlin, N. : Guanine in the Excreta of the Boll Weevil, 1403
Villa-Trevino, Dr. S., et *al.* : Biochemical Pathology of Acute Hepatic Adenosinetriphosphate Deficiency (substance of the Christian Herter Lecture, 1963), 34
Vince, M. A. : Synchronization of Hatching in American Bobwhite Quail (*Colinus virginianus*), 1192
Vinylic Resin Matrix : Additional Observations of Probable Stimulated Emission of a Terbium Ion Chelate in a (E. H. Huffman), 1373
Viral Antigen in a Cell by means of Double Radioactive Labelling : Recovery of the (Prof. V. M. Zhdanov, Y. M. Zhantieva and V. M. Stakhanova), 670
Viral Inhibitor of Plant Origin and Chick Interferon : Some Similarities between a (Dr. K. H. Fantes and C. F. O'Neill), 1048
Virus Lesions, Inhibition of Localized, by *N*-Dimethylaminosuccinamic Acid (Dr. J. G. Karas, C. L. Hamner, Prof. D. J. deZeeuw and H. M. Sell), 1197
Vision : Central Adaptation in Mechanisms of Form (Prof. D. M. MacKay), 993
Visual Critical Flicker Fusion Frequency by Intermittent Auditory Stimuli : Modification of (P. Turner and J. V. Smart), 1387
Visual Response to Gradients of Varying Colour and Equal Luminance (N. W. Daw), 215
Visual Stimuli While Problem Solving : Evoked Responses to Numerical and Non-numerical (Dr. R. M. Chapman and H. R. Bragdon), 115
Visual Stimulus : Incidence of Theta Rhythm prior to Awareness of a (Dr. N. F. Dixon and Dr. T. E. Lear), 167
Visual System : Ageing and Noise in the (Prof. M. A. Jeeves), 435
Vitamin A and Vitamin A Acid : A Biologically Active Metabolite of (K Yagishita et *al.*), 410
Vitamin A_2 from Fish Retinæ : Periodicity of Absorption Properties in Pigments based on (Dr. C. D. B. Bridges), 303
Vitamin B_{12} : Reaction of Tetrafluoroethylene with Pentacyanocobaltate Ions and with Reduced (M. J. Mays and Prof. G. Wilkinson), 1167
Vitamin C to Tomato Stems and Leaves : Feeding of (Prof. P. Hagene and J Trichet), 783
Vitamin E Deficiency : Adrenal Glands in : *in vitro* Corticoid Synthesis by Quartered Adrenal Glands of Rats deprived of Vitamin E (Dr. A. E Kitabchi), 650
Vitamin-binding Capacity of Experimentally Injured Liver (Dr. O. Frank, Dr. H Baker and Dr. C. M. Leevy), 302
